1 Introduction	1
1.1. Classification of Cyclonic Disturbances	1
1.2. Structure of Tropical Cyclone	2
1.2.1. Eye	3
1.2.2. Wall Cloud Region or Eye Wall	3
1.2.3. Rain/Spiral Bands	4
1.2.4. Outer Storm Area	5
1.2.5. Vertical Structure	5
1.3. Life Cycle of Tropical Cyclone	6
1.3.1 Formative Stage	7
1.3.2. Immature Stage	7
1.3.3. Mature Stage	7
1.3.4. Decaying Stage	8
1.4. Hazard due to Cyclone	8
1.4.1. Winds	10
1.4.2. Marine Impact	13
1.4.3. Rainfall	13
1.4.4. Storm Surge	14

1.5	Historical Cyclones and their Impact:.....	20
1.6.	Climatology of Tropical Cyclones	20
1.6.1.	Frequency of Disturbances	20
1.6.2.	Location of Genesis.....	20
1.6.3.	Intensification	23
1.6.4.	Movement	23
1.6.5.	Landfall	26
1.7.	Naming of Cyclones.....	29
1.8.	Early Warning System.....	30
2	Cyclone Warning Organisation	32
2.1	Milestones	32
2.2.	Organizational Structure.....	34
2.2.1.	Regional Specialized Meteorological Centre (RSMC)- Tropical Cyclones, New Delhi.....	34
2.2.2.	Cyclone Warning Division	36
2.2.3.	ACWCs/CWCs	36
2.2.4.	Other Offices	37
3	Needs for Monitoring and Prediction	39
3.1.	Data and Products	39
3.2.	Intensive Observational Phases (IOP)	44
3.3.	Manpower Needed.....	45
4	Observational Aspects of Cyclone Warning System	46
4.1.	Introduction	46
4.2.	Surface (Land, Ocean) Based Observations	47
4.2.1.	Land Based Conventional Surface Observatories	48
4.2.2.	Cooperative Cyclone Reporting Network of Stations.....	49
4.2.3.	Time of Observations	49

4.3. Ship Observations	50
4.3.1. Voluntary Observing Fleet (VOF).....	50
4.3.2. Recording and Reporting of Ship Observations	50
4.4. Data Buoy Network	51
4.5. Tide Gauges	52
4.6. Reports from Airport Meteorological Offices	52
4.7. Special Observations from Coastal Stations.....	54
4.7.1. Need for Special Observations	54
4.7.2. General Instructions.....	54
4.7.3. Discretion of Storm Warning Officer.....	55
4.7.4. Role of Special Observations in Determining the Period of Landfall	55
4.7.5. Importance of 24 hr Pressure Change ($P_{24}P_{24}$)	55
4.7.6. Discontinuance of Special Observations	55
4.8. Automatic Weather Stations.....	56
4.9. Upper Air Observations.....	57
4.9.1. Pilot Balloon Observatories	57
4.9.2. Radiosonde/Radiowind Observations	57
4.9.3. Wind Profilers	58
4.10. Microseism Observations	60
4.11. Quality Control of Observations.....	60
4.12. Radar Observations.....	61
4.12.1. Tracking by S-band Radars and Doppler Radars	61
4.12.2. Radars in Neighbouring Countries.....	65
4.12.3. X-Band Radars.....	65
4.12.4. Operation of Radar and Availability of Radar Observations	66
4.12.5. Radar Bulletin	67
4.13. Satellite Cloud Imagery Data and Derived Products Useful in Cyclone Warning	67

4.13.1. Cloud Imagery Data.....	67
4.13.2. Derived Products Used for Diagnosing a Tropical Cyclone	69
4.13.3. Tropical Cyclone Bulletins Based on Satellite Cloud Imagery Data and Derived Products.....	71
Appendix 4.1. List of Coastal stations in India	73
Appendix 4.2. List of Foreign Coastal stations	76
Appendix 4.3. List of Co-operative Cyclone Reporting Network of Stations (Andhra Pradesh & Orissa).....	78
5 Monitoring and Prediction Technique	79
5.1. Monitoring and Prediction of Cyclogenesis.....	79
5.1.1. Road Map	79
5.1.2. Tools to Use for Tropical Activity Daily Watch	82
5.1.3. Methodology for Tropical Activity Daily Watch	83
5.2. Monitoring of Cyclonic Disturbances (Depression and Above).....	83
5.2.1. Synoptic Analysis.....	85
5.2.2. Satellite Analysis.....	85
5.2.2.1. Position and Intensity of a Tropical Cyclone by Dvorak Technique.....	86
5.2.3. Radar Techniques for Fixing Centre and Intensity of Cyclone	89
5.3. Characteristics of Cyclonic Disturbance.....	91
5.3.1. Maximum Wind	91
5.3.2. Estimated Central Pressure (ECP).....	91
5.3.3. Pressure Drop ΔP	91
5.3.4. Radius of Maximum Wind (RMW).....	91
5.3.5. Heavy Rain	91
5.3.6. State of Sea.....	91
5.4. Prediction of Characteristics of Cyclonic Disturbances	92
5.4.1. TC Analysis Tools and Techniques.....	93
5.4.2. Cyclone Track Forecasting	95

5.4.3. Cone of Uncertainty in Track Forecast	98
5.4.4. Intensity Forecasting.....	99
5.4.4.1. Statistical Dynamical Model for Cyclone Intensity Prediction ..	100
5.4.5. Quadrant Wind Forecasting	100
5.4.6. Prediction of Heavy Rainfall.....	102
5.4.7. Prediction of Gale Wind at Landfall.....	103
5.4.8. Storm Surge.....	104
5.4.8.1. Nomograms.....	104
5.4.8.2. IIT Delhi Storm Surge Model	104
5.5. Check List for Decision Making	106
6 Bulletins and Warnings	113
6.1 Introduction	113
6.2. Bulletins Issued by RSMC, New Delhi.....	113
6.2.1. Tropical Weather Outlook.....	114
6.2.2. Tropical Cyclone Advisories.....	115
6.2.3. Tropical Cyclone Advisories for Civil Aviation	117
6.3. Global Maritime Distress Safety System (GMDSS).....	118
6.3.1. Transmission of GMDSS Bulletin.....	118
6.3.2. Frequency of Broadcasts	118
6.3.3. Modality of Transfer of GMDSS Bulletin to CES ARVI	118
6.3.4. Sample of GMDSS Bulletin	121
6.4. Bulletin for India Coasts	121
6.4.1. Four Stage Warning Bulletin Issued by Cyclone Warning Division	121
6.4.2. DGM's Bulletin for High Govt. Officials	122
6.4.3. Bulletin through SMS.....	122
6.4.4. Personal Briefing.....	124
6.4.5. Press Conference	124

6.5. User Specific Bulletins Issued by ACWCs/CWCs	124
6.5.1. Four Stage Warning Bulletin	124
6.5.2. Sea Area Bulletin	126
6.5.3. Coastal Weather Bulletins	129
6.5.4. Fleet Forecast for Indian Navy	130
6.5.4.1. Items in Fleet Forecast.....	131
6.5.4.2. Mode of Transmission of Fleet Forecast to Naval W/T Mumbai	132
6.5.5. Warnings to Ports	132
6.5.5.1. Hoisting of Signals	132
6.5.5.2. Frequency of Issue and Contents of Port Warning Bulletin	134
6.5.5.3. Format for Port Warning	134
6.5.6. Warnings for Fisheries	135
6.5.6.1. Criteria for Warnings	135
6.5.6.2. Warnings through FAX.....	135
6.5.6.3. Format for Fisheries Warning	135
6.5.7. Bulletins for All India Radio (AIR).....	136
6.5.7.1. Format for Cyclone Alert/Warning Bulletin for AIR/Press/Public	136
6.5.8. Coastal Bulletins for AIR News Cycle	136
6.5.9. Registered/Designated Warnees	137
6.5.10. Press Bulletins	137
6.5.11. Aviation Warnings	137
6.5.12. Bulletin through Satellite Based Cyclone Warning Dissemination System (CWDS)	137
6.5.13. Personal Briefing	137
6.5.14. Bulletin through SMS.....	138

6.6. Other Products Generated by Cyclone Warning Division, New Delhi.....	138
6.6.1. Track and Cone of Uncertainty.....	139
6.6.2. Ship Avoidance Guidance	139
6.6.3. Tropical Cyclone (TC) Vitals	139
6.6.3.1. Format of TC Vitals	139
6.6.4. Storm Surge Warning.....	140
6.6.5. Heavy Rainfall Warning.....	140
6.6.6. Gale Wind Warning	142
6.6.7. Crucial Observations	142
6.6.8. Satellite and Radar Features.....	142
6.6.9. Prognosis and Diagnosis.....	143
6.6.10. Significant Past Weather	143
6.7. Damage Potential and Action Suggested in the Bulletin	143
6.8. Time of Issue of Bulletins	143
6.9. Numbering of Bulletins.....	143
6.10. Reference Time	143
6.11. Terminologies in the Bulletins.....	143
6.12. Check List for Procedures	147
7 Cyclone Warning Dissemination	149
7.1. Cyclone Warning Dissemination	149
7.1.1. Cyclone Warning Dissemination System (CWDS)	152
7.1.2. Digital Meteorological Data Dissemination.....	152
8 Pre-cyclone Exercise	154
8.1. Telecommunications	154
8.2. Publicity and Broadcast of Warnings	154
8.3. Observational Data and Organisation	155
8.4. Reference Publications and Forms	155

8.5. Cyclone Manual	156
8.6. Telephone Fax and E-mail Address	156
8.7. Staff Matters	156
8.8. Circular Letter to Warnees	156
8.9. Ports	157
8.10 Meeting with the Chief Secretaries of the Maritime States	158
8.11. Visit to Coastal Radio Station	159
8.12. User's Workshop	159
9 Post Cyclone Action	160
9.1. Preliminary and Final Reports	160
9.2. Press Bulletin	162
9.3. Final Report	162
9.4. Scrutiny of Action Taken by ACWC/CWC	163
9.5. Visit of Officer to Cyclone Affected Areas	163
9.5.1. Assessment of Damage	163
9.5.2. Purpose of Survey	163
9.5.3. Annual Cyclone Review Meeting	164
9.5.4 Back-plotting and Re-analysis	165
Appendix A: (Preliminary Report).....	166
Appendix B: (FINAL REPORT)	167
10 Management of Cyclone and Common Man	169
10.1. Steps to be Taken Before the Cyclone	169
10.2. Steps to be Taken During the Cyclone	169
10.3. Steps to be Taken After Cyclone	170
10.4. Linkage of IMD with Cyclone Disaster Management	171
11 Conclusions and Future Scope.....	172

VIS	Visible
VOF	Voluntary Observing Fleet
VVP(Z)	Volume Velocity Processing
WMO	World Meteorological Organisation
WRF	Weather Research and Forecasting Model
WV	Water Vapour
WVWs	Water Vapour Winds

Preface

A tropical cyclone (TC) unleashes its highest destructive potential as it makes landfall in the coastal belt. Violent winds, torrential rains and storm surge are the three major causes of destruction. Though fewer tropical cyclones occur in the north Indian Ocean (NIO) compared to the other basins, the shallow depth of the Bay of Bengal and the low flat coastal terrain produce much larger storm surge and take a very heavy toll of life.

Among all the natural disasters related to water and weather, tropical cyclones are the only ones which allow two to three days time for preparedness measures and advance actions to be taken. Over the years, the India Meteorological Department (IMD) has built up a credible Cyclone Warning System for the country which uses advanced technologies like Automatic Weather Stations (AWS), Satellites, Radars, Numerical Weather Prediction (NWP) models and telecommunication systems. In the event of an approaching TC, IMD informs and warns all the concerned sectors in the government, the local population and media, through a variety of communicational channels.

Various components of early warning system for TC include (i) monitoring and prediction, (ii) warning organization, (iii) warning generation, presentation & dissemination, (iv) co-ordination with disaster management agencies, (vii) public education & reaching out and (viii) post-event review. All these aspects of the early warning system of TC are standardized to improve the efficiency of warning operation. Cyclone Warning Division of IMD has prepared this document on “Cyclone Warning in India: Standard Operation Procedure” incorporating all the above aspects. It is hoped that the information it contains will be useful to officials, agencies and NGOs engaged in disaster mitigation work for long-term planning, crisis management and the enlightenment of the public.

LS Rathore

July 2013

Director General of Meteorology

Acknowledgements

I am thankful to the authors for their unrelenting cooperation in the extensive effort that went into the formulation of the Manual entitled “Cyclone Warning in India-Standard Operation Procedure”. I would like to place on record the significant contributions made by the Cyclone Warning Division, IMD to bring out this document.

I put my appreciation on record for the valuable contributions made by Dr. M. Mohapatra towards preparation, compilation, edition, review and publication of this manual. I express my sincere thanks and appreciation to Dr. Sathi Devi and Dr. Naresh Kumar for their significant contribution as resource persons in preparation of this manual. I am thankful to Sh. B. K. Bandyopadhyay, Dr. Y. E. A. Raj and Dr. A. B. Majumdar for reviewing and adding values to the manuscript. I express my gratitude to (AVM) Dr. Ajit Tyagi (Retd. DGM) for his valuable initiative in preparation of this document. I also thank Mrs. Monica Sharma, Shri R.P.Sharma, Shri D.P. Nayak and Sh.R.G.Bali for their technical support in publication of this document.

L.S.Rathore

Introduction

A “Cyclonic Storm” or a “Cyclone” is an intense vortex or a whirl in the atmosphere with very strong winds circulating around it in anti-clockwise direction in the Northern Hemisphere and in clockwise direction in the Southern Hemisphere. The word “Cyclone” is derived from the Greek word ‘Cyclos’ meaning the coil of a snake. To Henri Paddington, the tropical storms in the Bay of Bengal and in the Arabian Sea appeared like the coiled serpents of the Sea and he named these storms as “Cyclones”. Tropical cyclones are also referred to as ‘Hurricanes’ over Atlantic

Ocean, ‘Typhoons’ over Pacific Ocean, ‘Willy-Willies’ over Australian Seas and simply as ‘Cyclones’ over north Indian Ocean (NIO).

1.1. Classification of Cyclonic Disturbances

Cyclones are intense low pressure areas - from the center of which pressure increases outwards. The amount of the pressure drop in the center and the rate at which it increases outwards gives the intensity of the cyclones and the strength of winds. The

Table 1.1. Criteria for classification of cyclonic disturbances over the North Indian Ocean

Type of disturbance	Associated maximum sustained wind (MSW)
1. Low Pressure Area	Not exceeding 17 knots (<31 kmph)
2. Depression	17 to 27 knots (31-49 kmph)
3. Deep Depression	28 to 33 knots (50-61 kmph)
4. Cyclonic Storm	34 to 47 knots (62-88 kmph)
5. Severe Cyclonic Storm	48 to 63 knots (89-117 kmph)
6. Very Severe Cyclonic Storm	64 to 119 knots (118-221 kmph)
7. Super Cyclonic Storm	120 knots and above (≥222 kmph)

Fig.1.1. Schematic diagram of a cyclone

criteria followed by the India Meteorological Department (IMD) to classify the low pressure systems in the Bay of Bengal and in the Arabian Sea as adopted by the World Meteorological Organisation (W.M.O.) are given in Table 1.1.

1.2. Structure of Tropical Cyclone

Tropical Cyclones are warm core low pressure systems having a large vortex in the atmosphere, which is maintained by the release of latent heat by convective clouds that form over warm oceans. In the northern hemisphere, the winds in a cyclone blow anticlockwise in the lower troposphere and clockwise in the upper

troposphere. However, in the southern hemisphere, the winds of the cyclone blow in the opposite direction i.e. clockwise in the lower levels and anticlockwise in the upper levels.

A full-grown cyclone is a violent whirl in the atmosphere with 150 to 1000 km diameter and 10 to 15 km height. Gale winds of 150 to 250 kmph or more spiral around the center of very low pressure area with 30 to 100 hPa below the normal sea level pressure. In a fully developed cyclonic storm, there are four major components of horizontal structure viz. Eye, Wall cloud region, Rain/Spiral bands and Outer storm area. A schematic diagram is given in Fig. 1.1.

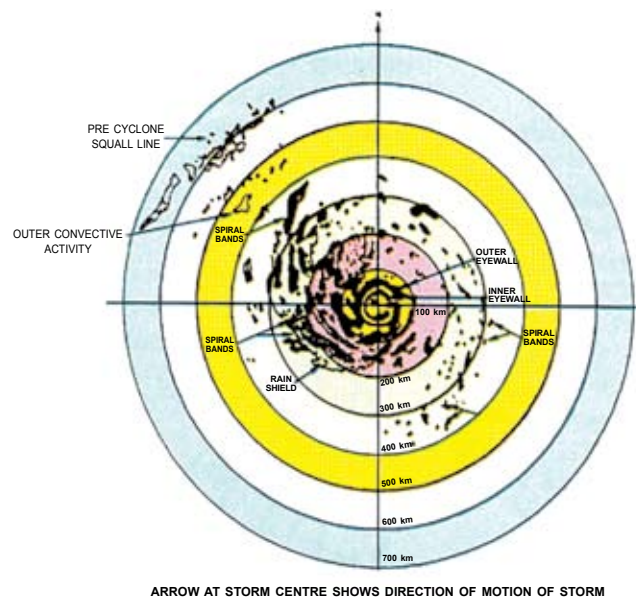

Fig.1.2. Composite structure of cyclone as seen in Radar imagery

1.2.1. Eye

A typical imagery of cyclone showing eye is given in fig.1.2. The most spectacular part of a matured cyclonic storm is its 'eye', which forms at the centre of the storm inside a Central Dense Overcast (CDO) region. The eye has a diameter of about 10 to 50 km, which is generally cloud free and is surrounded by thick wall clouds around it. It resembles an 'eye' when viewed in a satellite picture. It is a calm region with practically no rain. It is warmer than the surrounding region. The lowest estimated central pressure of 911 hPa was observed in case of Andhra cyclone of November 1977 followed by 919 hPa in the False Point cyclone (Odisha) in September 1885. The eye is generally seen when the storm is severe and the surface pressure falls below 980 hPa in the

Indian Ocean areas. Sometimes, a double eye wall structure can also be seen when the storm becomes very intense.

1.2.2. Wall Cloud Region or Eye Wall

The eye is surrounded by a 10-15 km thick wall of convective clouds where the maximum winds occur. This is the most dangerous part of a cyclonic storm. The height of the wall goes up to 10 to 15 km. The intense convection in this wall cloud region produces torrential rain, sometimes of the order of 50 cm in 24 hrs. The 'Storm surge' associated with a cyclonic storm, responsible for 80% loss of human lives, occurs in the eye wall region. The exact position of this eye wall is identifiable with the Cyclone Detection Radars (CDR), as the Radius of Maximum Reflectivity (RMR)

Fig. 1.3. INSAT imagery of Odisha Super cyclone (25-31 Oct, 2009) showing eye of the cyclone

of radar beam coincides with the Radius of Maximum Wind (RMW) in a cyclonic storm.

1.2.3. Rain/Spiral Bands

Beyond the eye wall region, the major convective clouds in a cyclonic storm, responsible for heavy rains, have a spirally banded structure. These spiral bands are sometimes hundreds of kilometres long and a few kilometres wide. The spiral bands are easily identifiable in radar and satellite pictures (Figs.1.2 and 1.3), as a number of

thunderstorm cells (Cumulonimbus clouds) are embedded in them that produce heavy rainfall (typical rate 3 cm/hr, which in extreme cases may reach upto 10 cm/hr).

These spirals also continuously change places and orientation with respect to the centre and rotate around it. The winds in this region continue to spiral around the centre with decreasing wind speed away from the centre. A dense cirrus shield of 400 to 500 km in diameter generally covers the central region along with the inner portion of the spiral bands.

Fig. 1.4. Vertical structure of a cyclone

1.2.4. Outer Storm Area

This region is beyond 250 km from the centre, where the wind is cyclonic but wind speed decreases slowly outside. The typical 10 metre horizontal wind distribution with a cyclone is shown in fig1.4. The weather conditions in the outer storm area

are better with scattered cumulus growth interspersed with spiral bands.

1.2.5. Vertical Structure

The vertical structure of a cyclonic storm (Fig.1.4) can be divided into three layers viz. Inflow layer, middle layer and outflow layer.

- i) The lowest layer from the surface to about 3 km is called the 'Inflow layer' where wind flow is towards the centre and contains a pronounced component of radial wind ($-V_r$). Most of this inflow layer occurs in the planetary boundary layer where friction plays a great role.
- ii) The layer between 3 to 7.6 km is called the 'Middle layer' where the flow is mostly tangential with little or no radial component (inflow).
- iii) The layer above 7.6 km upto the top of the storm is called the 'Outflow layer'

where wind is anticyclonic (clockwise). Outflow is most pronounced around 12 km level. Maximum warming occurs in the upper troposphere around 10 km where temperature at times may be 15° C warmer than the environment.

1.3. Life Cycle of Tropical Cyclone

The average life span of a cyclonic storm over the NIO is about 4 to 5 days which can be divided into four stages:

- a) Formative Stage
- b) Immature Stage

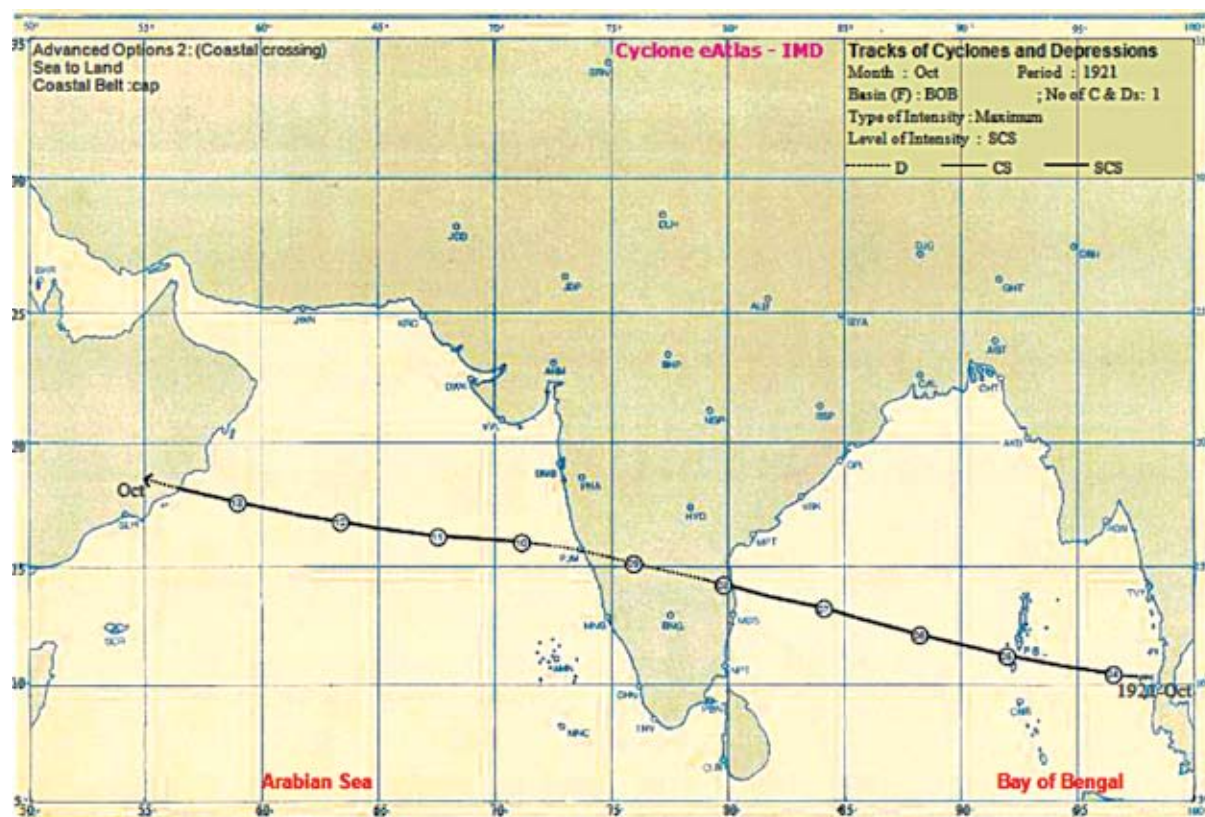

Fig. 1.5. Longest life period cyclone over the NIO

- c) Mature Stage
- d) Decaying Stage

The track of longest ever recorded cyclone over the NIO is shown in fig.1.5. It originated over the South China Sea, moved west-northwestwards across Vietnam, Bay of Bengal, South India and Arabian Sea to Oman during Oct. 1924.

1.3.1 Formative Stage

The Formative Stage covers the period from the genesis of a cyclonic circulation to the cyclonic storm stage through low pressure, depression and deep depression stages. Following factors are considered favourable for cyclogenesis.

- i. Coriolis Parameter
- ii. Low level positive vorticity
- iii. Weak vertical wind shear of horizontal winds
- iv. Warm Sea surface temperature ($> 26.5^{\circ}$ Celsius)
- v. Large convective instability
- vi. Large relative humidity at lower and middle troposphere

In general, cyclogenesis occurs over the warm oceanic regions away from the equator, where the moist air converges and weak vertical wind shear prevails. The cyclonic storm does not form near the equator, where the Coriolis force is zero. A little Coriolis force which is directly

proportional to the sine of latitude angle ($^{\circ}$), is required for turning of winds and hence formation of cyclonic storm. Pressure falls gradually during formative stage. Unusual pressure fall near the easterly wave, asymmetric strengthening of wind, elliptic or circular wind circulation over Inter-Tropical Convergence Zone (ITCZ - a region near equator where surface winds from both the hemispheres converge), isolated solid cloud mass in the satellite pictures are some of the indications of the cyclogenesis.

1.3.2. Immature Stage

In the Immature Stage, the central pressure of the system continues to fall till the lowest pressure is attained. The wind speed increases and usually at a distance of about 30-50 km from the centre a well developed eye wall is seen. Duration of this stage can be as long as 3 days. At times, it may be an explosive occurrence in which pressure fall of 40 to 50 hPa in a day may occur. The cloud and rain pattern changes from disorganised squalls to narrow organised bands spiraling inward.

1.3.3. Mature Stage

During the Mature Stage, no further fall of pressure and increase of wind speed occur. In some cases, winds of very severe cyclonic storm can extend upto several hundreds of kilometres from the storm centre to the right of the direction of motion of the storm in the northern hemisphere.

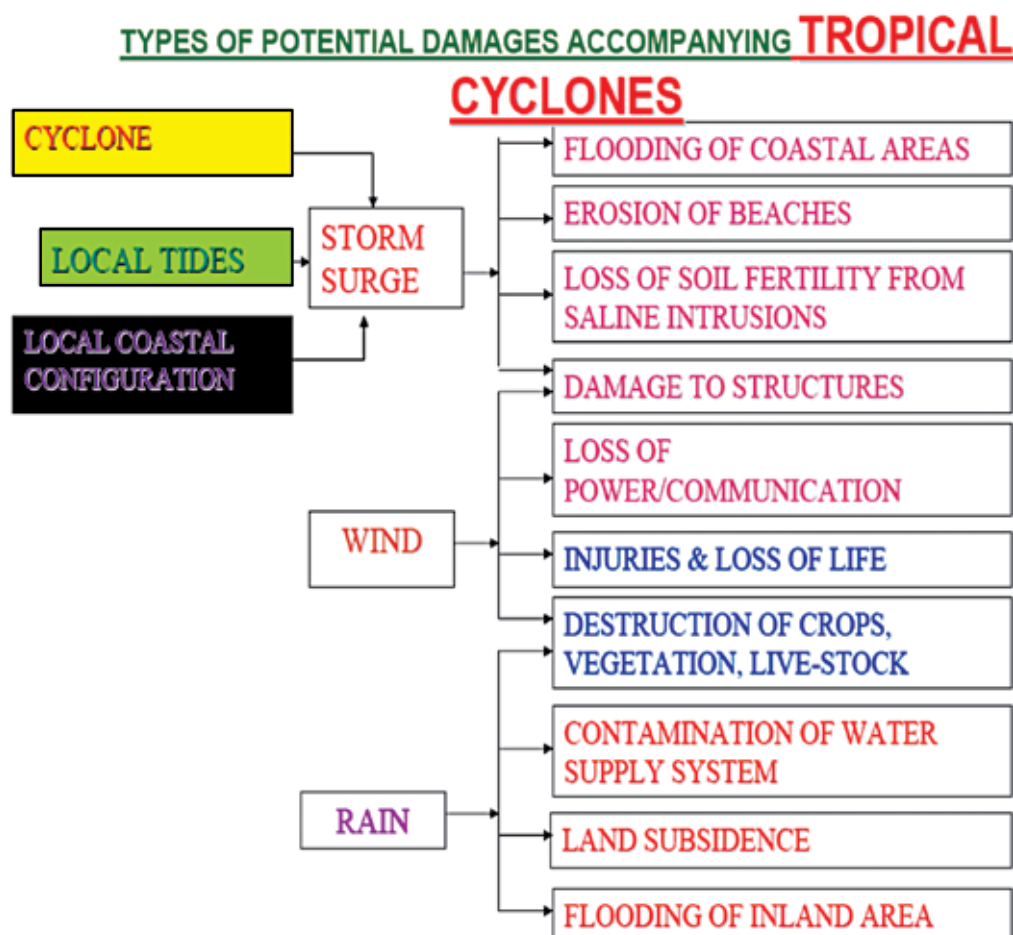

Fig. 1.6. Types of Potential Damages accompanying Tropical Cyclones

1.3.4. Decaying Stage

In the Decaying Stage, the tropical storms begin to lose their intensity when they move over to land, over colder water or lie under an unfavourable large-scale flow aloft. In some cases, they come under the influence of an upper air trough and recurve towards northeast. The storms weaken over land because of sharp reduction of moisture supply and increase in surface friction.

1.4. Hazard due to Cyclone

Disturbed weather occurs generally in association with low pressure systems that are seen over different parts of the globe. Areas of high pressure are characterized by fair weather. The severity of weather increases with the intensity of the low pressure. The cyclonic storms cause heavy rains, strong winds and also high seas and devastate coastal areas at the time of landfall, leading to loss of life and property.

Table 1.2. Storm Intensity, Expected Damage and Suggested Actions

Intensity	Damage expected	Action Suggested
Deep Depression 50 – 61 kmph (28-33 knots)	Minor damage to loose and unsecured structures	Fishermen advised not to venture into the open seas.
Cyclonic Storm 62 – 87 kmph (34-47 knots)	Damage to thatched huts. Breaking of tree branches causing minor damage to power and communication lines	Total suspension of fishing operations
Severe Cyclonic Storm 88-117 kmph (48-63 knots)	Extensive damage to thatched roofs and huts. Minor damage to power and communication lines due to uprooting of large avenue trees. Flooding of escape routes.	Total suspension of fishing operations. Coastal hutment dwellers to be moved to safer places. People in affected areas to remain indoors.
Very Severe Cyclonic Storm 118-167 kmph (64-90 knots)	Extensive damage to kutcha houses. Partial disruption of power and communication line. Minor disruption of rail and road traffic. Potential threat from flying debris. Flooding of escape routes.	Total suspension of fishing operations. Mobilise evacuation from coastal areas. Judicious regulation of rail and road traffic. People in affected areas to remain indoors.
Very Severe Cyclonic Storm 168-221 kmph (91-119 knots)	Extensive damage to kutcha houses. Some damage to old buildings. Large-scale disruption of power and communication lines. Disruption of rail and road traffic due to extensive flooding. Potential threat from flying debris.	Total suspension of fishing operations. Extensive evacuation from coastal areas. Diversion or suspension of rail and road traffic. People in affected areas to remain indoors.
Super Cyclone 222 kmph and more (120 knots and more)	Extensive structural damage to residential and industrial buildings. Total disruption of communication and power supply. Extensive damage to bridges causing large-scale disruption of rail and road traffic. Large-scale flooding and inundation of sea water. Air full of flying debris.	Total suspension of fishing operations. Large-scale evacuation of coastal population. Total suspension of rail and road traffic in vulnerable areas. People in affected areas to remain indoors.

The expected damage associated with the cyclonic disturbances of different intensities alongwith action suggested to disaster managers is given in Table 1.2. Types of damages associated with a tropical cyclone are also shown in fig.1.6. Detailed impacts of wind, rainfall and storm surge as well as marine impact are discussed in Section 1.4.1-1.4.4.

1.4.1. Winds

The damages produced by winds are extensive and cover areas occasionally greater than the areas of heavy rains and storm surges which are in general localized in nature. The impact of the passage of the cyclone eye, directly over a place is quite different from that of a cyclone that does not hit the place directly. The latter affects the location with relatively unidirectional winds i.e. winds blowing from only one side, and the lee side is somewhat protected. An eye passage brings with it rapid changes in wind direction, which imposes torques and can twist the vegetation or even structures. Parts of structures that were loosened or weakened by the winds from one direction are subsequently severely damaged or blown down when hit upon by the strong winds from the opposite direction. A partial eye passage can also do considerable damage, but it is less than a total eye passage.

As tropical cyclones have a circular shape, an eye passage over a location exposes it to the maximum possible duration of

destructive winds. The higher wind is also associated with convectively active eye-wall region and has higher wind gusts than outside it. The gustiness effect is amplified over land where friction reduces sustainable wind but not the peak gust. This widens the gap between the peak and the lull of the gusts even more, creating strong negative pressure forces on lee-side of buildings especially damaging metal sheet and wooden structures. Strong wind also exposes roofs to strong lifting forces. The typical damage to buildings is due to failure of roofing systems. Loss of roof irrespective of the material used, leads to water damage of the walls. When the roofs get blown off, the exterior walls lose the support provided by the roofing systems and collapse even in lesser wind intensity.

Winds are stronger in the right semi-circle with reference to the direction of motion of the cyclonic storm in the Northern Hemisphere. Occasionally, very strong winds are also encountered to the left side of the storm with respect to its motion. The total damage is significantly greater than that from the relatively unidirectional winds of a near miss with comparable intensity.

Under the action of wind flow, structures experience aerodynamic forces that include the drag force acting in the direction of the mean wind, and the lift force acting perpendicular to that direction. The structural response induced by the wind drag is commonly referred to as the 'along

(a)

(b)

Fig. 1.7. Damage caused by very severe cyclonic storm 'Nargis'

wind' response. It has been recognized that in the case of modern tall buildings which are more flexible, lower in damping, and lighter in weight than older structures, the natural frequency of vibration may be in the same range as the average frequency of occurrence of powerful gusts and therefore large resonant motions induced by the wind may occur. This must be taken into consideration in design of cyclone resistant buildings.

Many of the overhead communication networks are susceptible to damage when the winds reach 85 kts (158 kmph), This is especially the case for secondary telephone lines. Microwave towers are susceptible to misalignment when winds reach 85 kts (158 kmph). This affects

local telephone, cellular service and long distance service. Microwave and radio towers are susceptible to destruction when winds reach 100 kts (186 kmph). At higher wind speed even larger antennas are also vulnerable and are blown off. Even large satellite communication dishes can be damaged in cyclones with sustained wind speeds of 135 kts (251 kmph). Coastal roads/locations are vulnerable to damage from inundation/waves run-up. The most detrimental hazards to roadways are uprooted trees, power poles and lines, and debris falling on roads and blocking them. This becomes a serious problem when winds reach 80 kts (149 kmph) or more. The typical examples of damage due to cyclone, Nagis in April-May 2008 are shown in fig.1.7

Table 1.3. Marine impact of cyclonic disturbances

S. N.	Intensity	Strength of wind(kmph/knots)	Satellite 'T' No.	Condition of Sea	Wave height (m)
1.	Depression	(i)(31- 40)/(17-21) (ii)(41- 49)/(22-27)	1.5	Moderate Rough	1.25-2.5 2.5-4.0
2.	Deep Depression	(50–61)/(28-33)	2.0	Very Rough	4.0-6.0
3.	Cyclonic Storm	(62–87)/(34-47)	2.5-3.0	High	6.0-9.0
4.	Severe Cyclonic Storm	(88-117)/(48-63)	3.5	Very High	9.0-14.0
5.	Very Severe Cyclonic Storm	(i)(118-167)/(64-90) (ii)(168-221)/(91-119)	4.0-4.5 5.0–6.0	Phenomenal Phenomenal	Over 14.0
6.	Super Cyclonic Storm	(222/120 and more)	6.5 and more	Phenomenal	Over 14.0

1.4.2. Marine Impact

The wind speed, condition of Sea and wave height associated with 'T' numbers of various categories of cyclonic disturbances, are given in Table 1.3. Condition of the sea becomes high to Phenomenal with wave height of 6 metre or more during cyclone period.

1.4.3. Rainfall

Rainfall is generally very heavy and spread over a large area thus leading to excessive amount of water. Rains (sometimes even

more than 30 cm per 24 hrs) occur in association with cyclones. Unabated rains give rise to unprecedented floods. Rainwater on the top of storm surge may add to the fury of the storm. Rain is an annoying problem for the people who become shelterless due to a cyclone. It creates problems in post cyclone relief operations also. A typical example of flood due to cyclone is show in fig. 1.8.

On the infrastructure front, the most critical problem after passage of any cyclone is the restoration of water distribution system. Strong winds along with heavy

Fig. 1.8. Flood caused by Odisha super cyclone, 25-31 October 1999

rains accompanied with floods/storm surge associated with the cyclone, devastate the critical parts of the power generation and distribution systems. Even the strongest port and airport facilities, fuel and water storage tanks, high voltage transmission tower, etc., are vulnerable to damage.

Soil erosion also occurs on a large scale. Heavy rains log the ground and cause softening of the ground due to soaking. This contributes to weakening of the embankments, the leaning over of utility poles or collapse of pole type structures.

1.4.4. Storm Surge

Storm surge is the major cause of devastation from tropical storms. Though, the deaths and destruction are caused directly by the winds in a tropical cyclone as mentioned above, these winds also lead to massive piling of Sea water in the form of what is known as storm surge that

lead to sudden inundation and flooding of coastal regions.

The surge is generated due to interaction of air, sea and land. When the cyclone approaches near the coast, it provides the additional force in the form of very high horizontal atmospheric pressure gradient which leads to strong surface winds. As a result, sea level rises. It continues to rise, as the cyclone moves over shallower waters and reaches a maximum on the coast near the point of landfall. Storm surge is inversely proportional to the depth of Sea water. The depth varies from about 500 m at about 20° N in the north central Bay to about 5 m along the West Bengal-north Odisha coast. Because of the vast shallow continental shelf, the storm surges get amplified significantly in these areas. The northward converging shape of the Bay of Bengal provides another reason for the enhanced storm surge in these areas. There is another cause of sea level rise,

Fig. 1.9. Impact of storm surge caused by Very severe cyclonic storm 'Nargis'

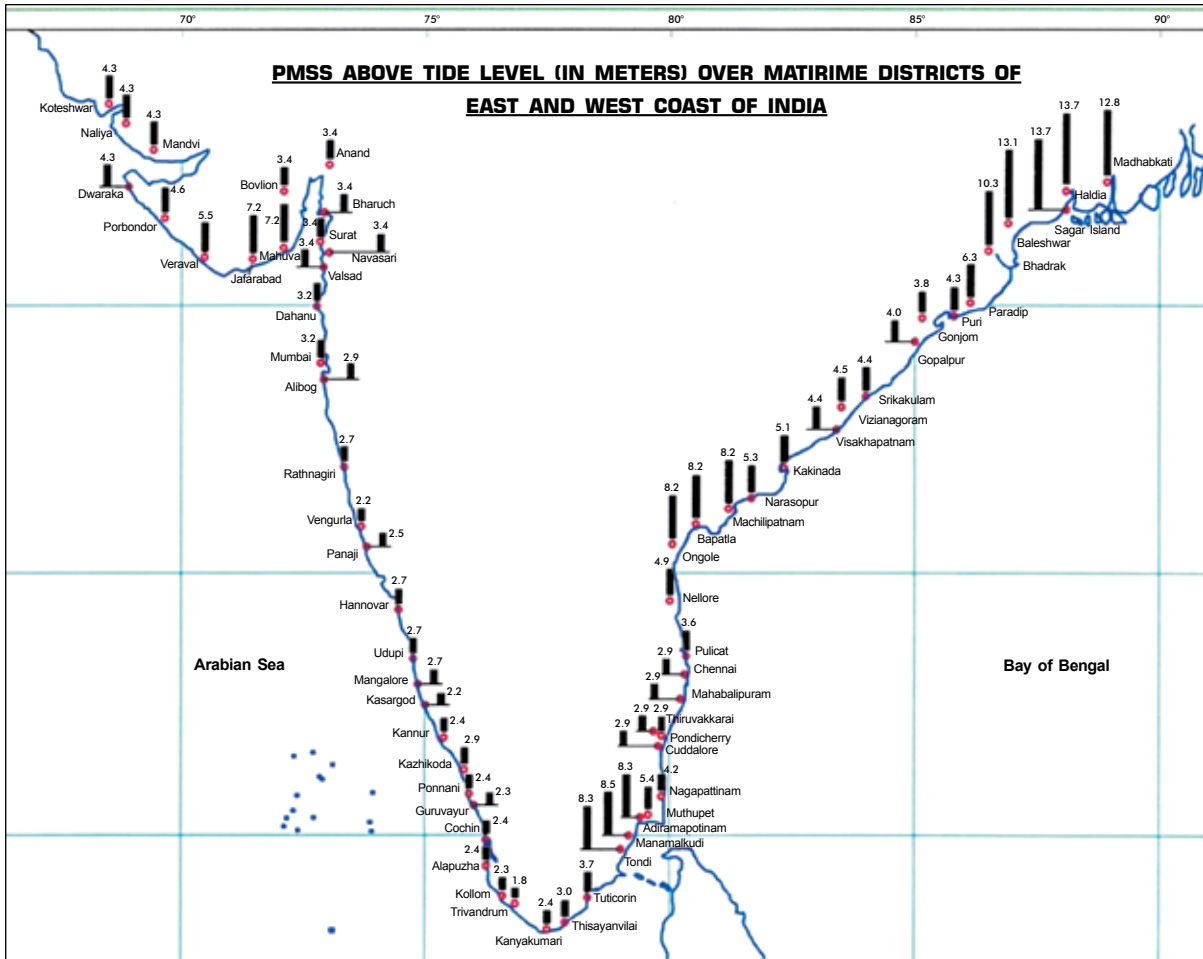

Fig. 1.10. Probable maximum storm surge (PMSS) above tide levels (In metres) over maritime districts of east and west coasts of India

viz., astronomical tide, which is well known. The rise due to high tide may be as high as 4.5 m above the mean sea level at some parts of Indian coast. The worst devastation is caused when the peak surge occurs at the time of high tide. As the leading edge of the storm surge crashes against the coastline, the speed of the surge puts great stress on the walls.

The debris like uprooted trees, fences and parts of broken houses, act as battering rams and cause further damage. The sand

and gravel carried by the moving currents at the bottom of the surge can cause sand papering action of the foundations. The huge volume of water can cause such pressure difference that the house “floats” and once the house is lifted from the foundations, water enters the structure that eventually collapses.

The Probable Maximum Storm Surge (PMSS) for east and west coasts of India are shown in Fig. 1.10.

Table 1.4(a). Historical records of 12 most devastating cyclonic storms, which formed in the Bay of Bengal and made landfall on the East coast of India

S. N.	Date/Year	Category of Cyclone	Landfall and Relevant information
1	7–12 October, 1737	Super Cyclonic Storm	Crossed West Bengal coast over Sunderbans Surge height : 12 M Loss of life : 300,000
2	31 October, 1831	Very Severe Cyclonic Storm	Crossed Odisha coast near Balasore Surge height : 2 – 5 m Loss and damage: People killed - 22,000 Cattle heads lost - 50,000
3.	2–5 October, 1864	Very Severe Cyclonic Storm	Crossed West Bengal coast near Contai Surge height: The maximum height of the waves reached 12 m. Loss and damage, People killed - 50,000 (mostly due to drowning), and 30,000 (due to diseases as a result of inundation)
4.	1–2 November, 1864	Severe Cyclonic Storm	Crossed Andhra Pradesh coast near Machilipatnam Surge height: 4 m. Loss and damage : People killed - 30,000
5.	22 September, 1885	Super Cyclonic Storm	Crossed Odisha coast near False Point, Central pressure : 919 hPa, Surge height: 7 m. Loss of life : 5000
6.	14–16 October, 1942	Severe Cyclonic Storm	Crossed West Bengal coast near Contai Surge height : 3 – 5 m Loss and damage : People killed – 19,000 Cattle heads killed - 60,000
7.	8–11 October, 1967	Severe Cyclonic Storm	Crossed Odisha coast between Puri and Paradip on the morning of 9 October and then crossed Bangladesh coast during the night of 10 – 11 October. Loss and damage: People killed - 1,000, Cattle heads lost 50,000.
8.	26–30 October, 1971	Severe Cyclonic Storm	Crossed Odisha coast near Paradip early morning of 30 October Maximum wind: 150-170 kmph (81-92 kts.) Surge height : 4 – 5 m, north of Chandbali Loss and damage: People killed – 10,000; Cattleheads lost – 50,000; Houses damaged – 8,00,000

S. N.	Date/Year	Category of Cyclone	Landfall and Relevant information
9.	14-20 November, 1977	Super Cyclonic Storm	<p>Crossed Andhra Pradesh coast Nizampatnam at 1730 IST on 19 November.</p> <p>Maximum wind : Ongole: 102 kmph (55 kts.) Machilipatnam: 120 kmph (65 kts); Gannavaram: 139 kmph (75 kts.)</p> <p>Surge height : 5 m</p> <p>Intensity : T 7.0</p> <p>Maximum estimated wind speed: 260 kmph (140 kts)</p> <p>Loss and damage: People killed - 10,000; Cattleheads – 27,000; Damage to crops and other property were estimated to be around Rs. 350 crores.</p>
10.	4 – 11 May, 1990	Super Cyclonic Storm*	<p>Crossed Andhra Pradesh coast at about 40 km south west of Machilipatnam around 1900 IST of 9 May</p> <p>Maximum wind : Machilipatnam: 102 kmph (55 kts); Gannavaram: 93 kmph (50 kts)</p> <p>Maximum estimated wind speed : 235 kmph (126 kts)</p> <p>Surge height : 4 – 5 m</p> <p>Intensity : T 6.5</p> <p>Loss and damage : People killed – 967; the estimated cost of the damages to crops and properties - Rs. 2,248 crores.</p>
11.	5 – 6 November, 1996	Very Severe Cyclonic Storm	<p>Crossed Andhra Pradesh coast near Kakinada at midnight of 6 November</p> <p>Maximum wind:200 kmph (108 kts)</p> <p>Surge height : 3 – 4 m</p> <p>Loss and damage : People killed – 2000; People missing - 900; crops destroyed in 3,20,000 hectares of land; house destroyed – 10,000</p> <p>Estimate of the loss for crops - Rs. 150 crores</p>
12.	25 – 31 October, 1999	Super Cyclonic Storm	<p>Crossed Odisha coast near Paradip at noon of 29 October.</p> <p>Maximum wind : 260 kmph (140 kts); Bhubaneswar: 148 kmph (80 kts)</p> <p>Surge height : 6 – 7 m</p> <p>Intensity : T 7.0</p> <p>Loss and damage : People killed = 9,885; People injured - 2,142; cattleheads perished - 3,70,297, Paddy crops in 16,17,000 hectares and other crop in 33,000 hectares damaged.</p>

Table 1.4(b). Historical records of 11 most devastating cyclonic storms, which formed in the Arabian Sea and made landfall on the West coast of India

S. No.	Date/Year	Category of Cyclone	Landfall and Relevant information
1.	16 May 1618	Severe Cyclonic Storm	Crossed near Bombay (Mumbai) coast Loss and damage : People killed - 2,000
2.	30 October – 2 November, 1854	Severe Cyclonic Storm	Crossed near Bombay (Mumbai) coast on 1 November Loss and damage : People killed - 1,000 Property worth crores of rupees perished within four hours.
3.	18 – 23 November, 1948	Severe Cyclonic Storm	Crossed Maharashtra coast near Virar, 72 km north of Bombay (Mumbai) at about 0830 hrs. IST on 22 November. Maximum wind : Colaba: 120 kmph (65 kts) and Juhu: 151 kmph (81 kts.) Loss and damage : Great havoc and heavy loss of life and property and all means of traffic and communication were completely paralysed for two days. A number of small vessels and crafts capsized in the water of Bombay (Mumbai) harbour. Thousands of big trees uprooted and hundreds of buildings and hutments were rendered uninhabitable.
4.	23 – 25 May, 1961	Severe Cyclonic Storm	Crossed Maharashtra coast near Devgad on the night of 24 to 25 May. Loss and damage: 5 Lakhs fruit trees were reported to have been razed to the ground. 1,700 houses completely and 25,000 houses partially damaged.
5.	9 – 13 June, 1964	Severe Cyclonic Storm	Crossed Gujarat coast just west of Naliya during the late forenoon on 12 June. Maximum wind : Naliya: 135 kmph (73 kts); Dwarka: 105 kmph (57 kts); Porbandar: 74 kmph (40 kts) and Veraval: 83 kmph (45 kts.) Surge height : 2 m at Kandla Loss and damage: People killed – 27
6.	19 – 24 October, 1975	Very Severe Cyclonic Storm	Crossed Saurashtra coast about 15 km to the northwest of Porbandar at 1500 hours IST of 22 October Maximum wind : Jamnagar: 160 – 180 kmph (86-97 kts) Porbandar: 110 kmph (59 kts) Surge height : 4 – 6 m at Porbandar and Okha Intensity : T 6.0

S. No.	Date/Year	Category of Cyclone	Landfall and Relevant information
			Loss and damage: People killed – 85; Several thousands of houses were damaged, Many trees/ electric/telephone poles/roof tops blew; A train was also blown off its rails; loss of property was estimated to be Rs. 75 crores.
7.	31 May – 5 June, 1976	Severe Cyclonic Storm	Crossed Saurashtra coast near Bhavnagar on 3 June. Maximum wind : Ship HAKKON MAGNUS: 167 kmph (90 kts) Loss and damage : People killed - 70 Cattleheads lost – 4500; Houses damaged - 25000 ; Damage estimated to be Rs. 3 crores.
8	14–20 November, 1977	Very Severe Cyclonic Storm *	Crossed Karnataka between Mangalore and Honavar in the early morning on 22 November. Intensity: T 5.5 Loss and damages : People killed - 72; 8,400 houses totally and 19,000 houses partially damaged; Loss estimated to be Rs. 10 Crores.
9.	4–9 November, 1982	Very Severe cyclonic Storm	Crossed Saurashtra coast, about 45 km east of Veraval on 8 November Loss and damage: People killed - 507 Livestock perished – 1.5 Lakh; Thousands of houses collapsed
10.	17-20 June, 1996	Severe Cyclonic Storm	Crossed south Gujarat coast between Veraval and Diu in the early morning of 19 June Intensity : T 3.5 Maximum wind : Veraval recorded 86 kmph (46 kts) at 0430 hrs IST of 19 June Storm surge : 5-6 m near Bharuch Loss and damage: People killed – 46 Cattle heads perished- 2113; No. of houses damaged – 29,595, loss of property - Rs. 18.05 Crore
11	4 – 10 June 1998	Very Severe Cyclonic Storm	Crossed Gujarat coast near Porbandar between 0630 and 0730 hrs IST of 9 June Intensity : T5.0 Maximum wind : Jamnagar : 183 kmph (98 kts) at 0730 hrs IST of 9 June Surge height : 2 – 3 m above the astronomical tide of 3.2 m; Loss and damage: People killed – 1173; People missing – 1774 Loss of property worth to be Rs. 18.65. Crore

1.5 Historical Cyclones and their Impact

The Indian Seas have historically been the deadliest basin with several cyclones responsible for more than 1 lakh of casualties. The 1970 Bhola cyclone killed about 3 lakhs people, perhaps, the maximum number as per the recorded history. Recently, cyclone, Nargis caused loss of 1,40,000 human lives in Myanmar in May 2008. After the availability of satellites for monitoring of cyclones, Odisha super cyclone of 1999 over the Bay of Bengal could be rated as the most intense tropical cyclone (TC) crossing Indian coast. Tables 1.4 (a) & 1.4(b) list some of the most intense TCs that had affected Indian coasts.

1.6. Climatology of Tropical Cyclones

1.6.1. Frequency of Disturbances

It is now a well known fact of climatology that nearly 7 % of the global TCs form in the NIO. About 5 to 6 TCs occur in the NIO annually. However, they prominently occur during the pre-monsoon Season (March-April-May) and the post-monsoon Season (October-November-December). The monthwise distribution of cyclonic disturbances over the NIO, Bay of Bengal and Arabian Sea are shown in Fig.1.11. The TCs develop in the ratio of 4:1 over the Bay of Bengal and the Arabian Sea.

It is seen that the annual number of distur-

bances has ranged from 8 to 23. The number of cyclonic storms has varied from a minimum of 1 in 1949 to a maximum of 10 each in the years 1893, 1926 and 1930. The average number of cyclonic disturbances and cyclonic storms per year is about 13.5 and 5 respectively. More than 80% of all cyclonic disturbances occur during the months of June to November with a maximum in August. The monthly frequency of cyclonic storms shows two maxima, i.e. in May and November.

The Bay of Bengal (BoB) is more prone for intense systems. Higher cyclonic disturbances (depressions and above) over the BoB is mainly due to the depressions/deep depressions during the monsoon season developed over this region and the remnants of the systems formed over the south China Sea and emerging into BOB after moving west-northwestwards across southeast Asia.

1.6.2. Location of Genesis

The frequency is very less over the west Arabian Sea mainly due to colder Sea Surface Temperature (SST). The genesis of cyclonic disturbances varies with respect to season. While genesis mostly takes place in lower latitudes in association with inter-tropical convergence zone (ITCZ) during pre-monsoon (March-May) and post-monsoon (October-December) seasons, it occurs over northerly latitude during monsoon season (June-September). This fact is illustrated in Fig.1.12.

Fig. 1.11(a). Monthly frequency of cyclonic disturbances over NIO during 1891-2011

Fig. 1.11(b). Monthly frequency of cyclonic disturbances over the BOB during 1891-2011

Fig. 1.11 (c). Monthly frequency of cyclonic disturbances over Arabian Sea during 1891-2011

Fig.1.11 (d). Monthly frequency of total cyclonic disturbances (depression and above) and total cyclones (Cyclonic storms and above) during 1891-2011 over NIO

1.6.3. Intensification

The probabilities of intensification of a depression into a cyclonic storm and severe cyclonic storm and cyclonic storm into a severe cyclonic storm in different months are shown in Fig.1.13. The probability is maximum in the month of April followed by March, May and November in case of depression to cyclone and in the month of May followed by April and November in case of depressions to severe cyclonic storm.

More than 50% of the cyclonic disturbances (CDs) that form in the months of March, April, May, November and December intensify into storms. A third of the Bay

CDs and half the number of the Arabian Sea CDs intensify into cyclones.

1.6.4. Movement

The tracks of cyclones over the NIO during 1891-2009 are shown in Fig 1.14(a). Recently an electronic atlas has been published for tracks of CDs over the Bay of Bengal and Arabian Sea. Analyses of storm tracks with reference to their genesis, recurvature and landfall points on $1^\circ \times 1^\circ$ scale along the Indian coasts have also been produced. Mostly the system developing over the NIO move in a northwesterly direction (Fig 1.14(a)). However, there are cases of recurvature

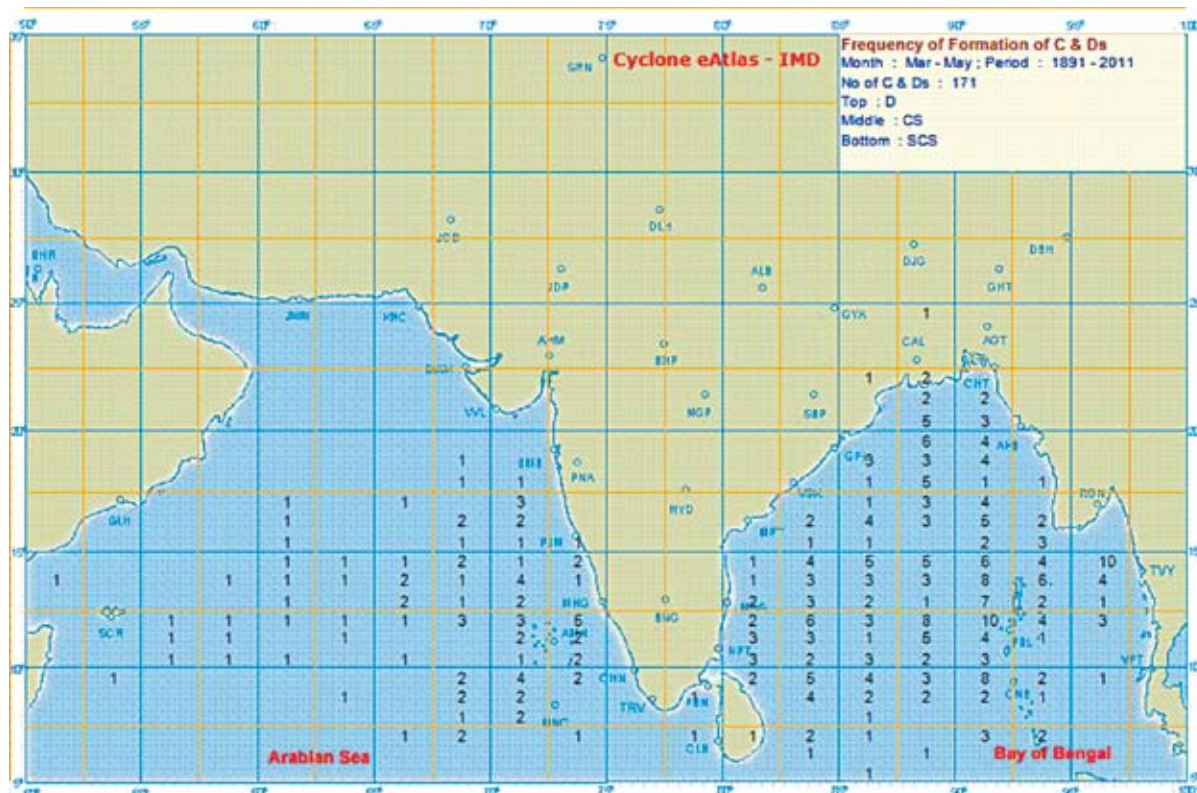

Fig. 1.12 (a). Frequency of genesis of cyclonic disturbances over the NIO during pre-monsoon season

Cyclone Atlas - IMD

Frequency of Formation of C & Ds
 Month : Oct - Dec ; Period : 1891 - 2011
 No of C & Ds : 528
 Top : D
 Middle : CS
 Bottom : SCS

Map showing the frequency of formation of Cyclones and Depressions (C & Ds) over the Indian subcontinent and surrounding waters (Arabian Sea and Bay of Bengal) from October to December, 1891-2011. The map is overlaid with a grid. Numbers in the cells represent the frequency of formation. The map is color-coded: blue for the sea, green for land, and yellow for the topography.

24

Fig. 1.13(a). Monthly Probability of intensification of depression into a cyclone

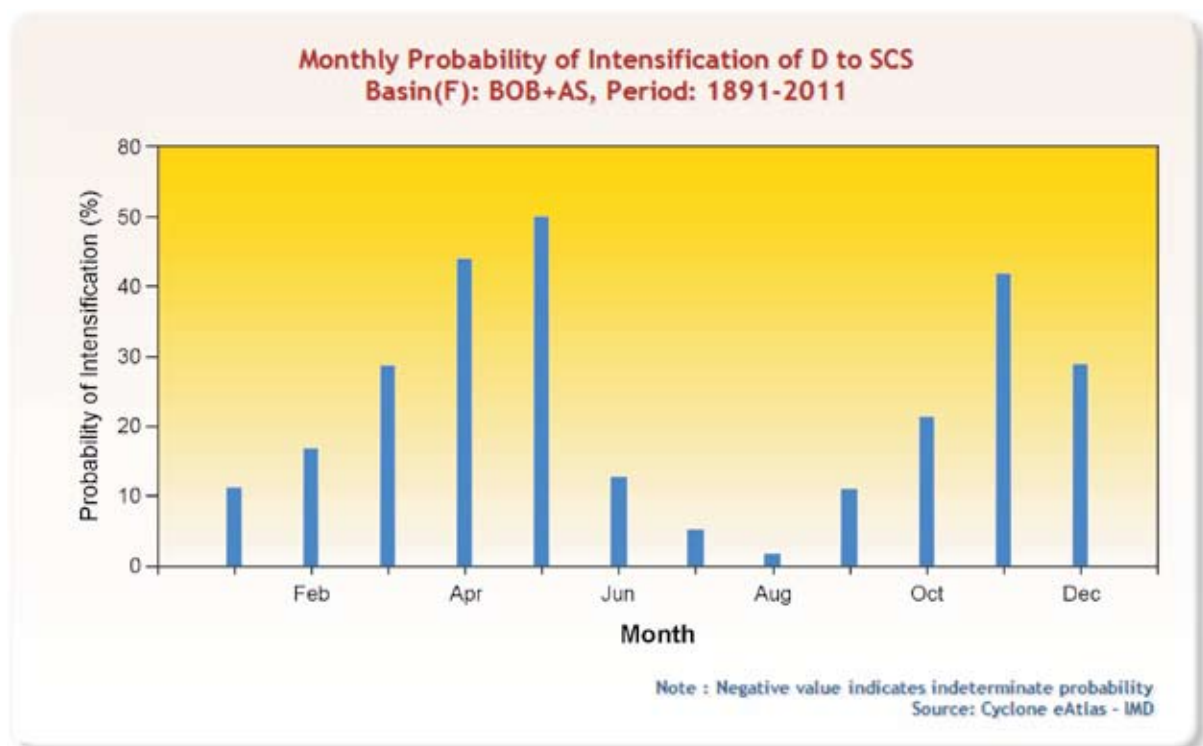

Fig. 1.13(b). Monthly Probability of intensification of depression into a severe cyclonic storm

Fig. 1.13 (c). Monthly Probability of intensification of cyclonic storm into a severe cyclonic storm

towards the northeast or east to the southwest. The frequency of recurvature is higher towards the northeast compared to southwest or east. It is found that the probability of recurvature is higher over the Arabian Sea when the system moves to the north of 15°N leading to more landfalls over Gujarat coast. Over the Bay of Bengal, there is no such preferred latitude/longitude for the recurvature of the system. However the probability of recurvature towards the northeast is higher during the pre-monsoon Season.

The probability of direction of movement of cyclonic disturbances over the north Indian Ocean based on cyclone e-Atlas is shown in Fig.1.14(b).

1.6.5. Landfall

The Bay of Bengal TCs more often strike Odisha-West Bengal coast in October, Andhra coast in November and the Tamilnadu coast in December. Over 62 percent of the TCs in the Bay of Bengal strike different parts of the east coast of India, 25 percent strike coasts of Bangladesh and Myanmar and about 13 percent dissipate over the sea itself. The cyclones crossing different coastal states are shown in Fig.1.15. Considering Arabian Sea, a significant number of cyclones dissipate over the sea itself before making any landfall (about 48.5%). Gujarat coast is most prone for the cyclones developing over the Arabian Sea, with about 23% of

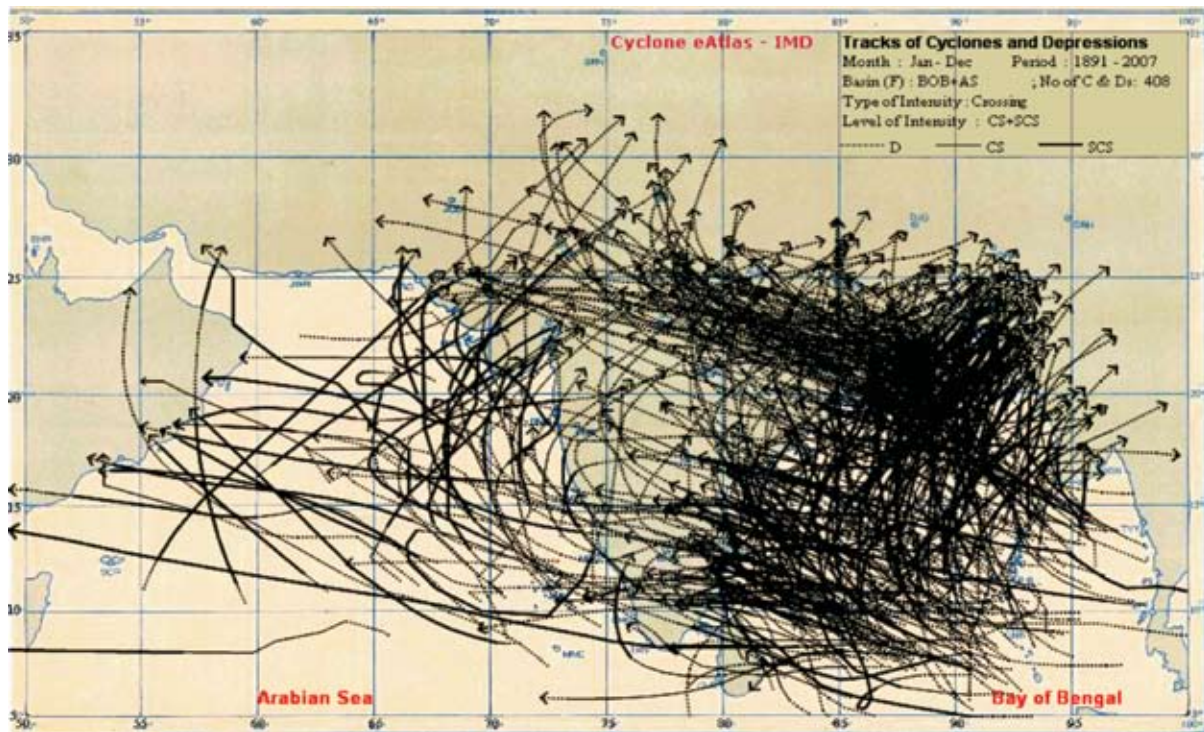

Fig. 1.14(a). Tracks of cyclones over the NIO during 1891-2009

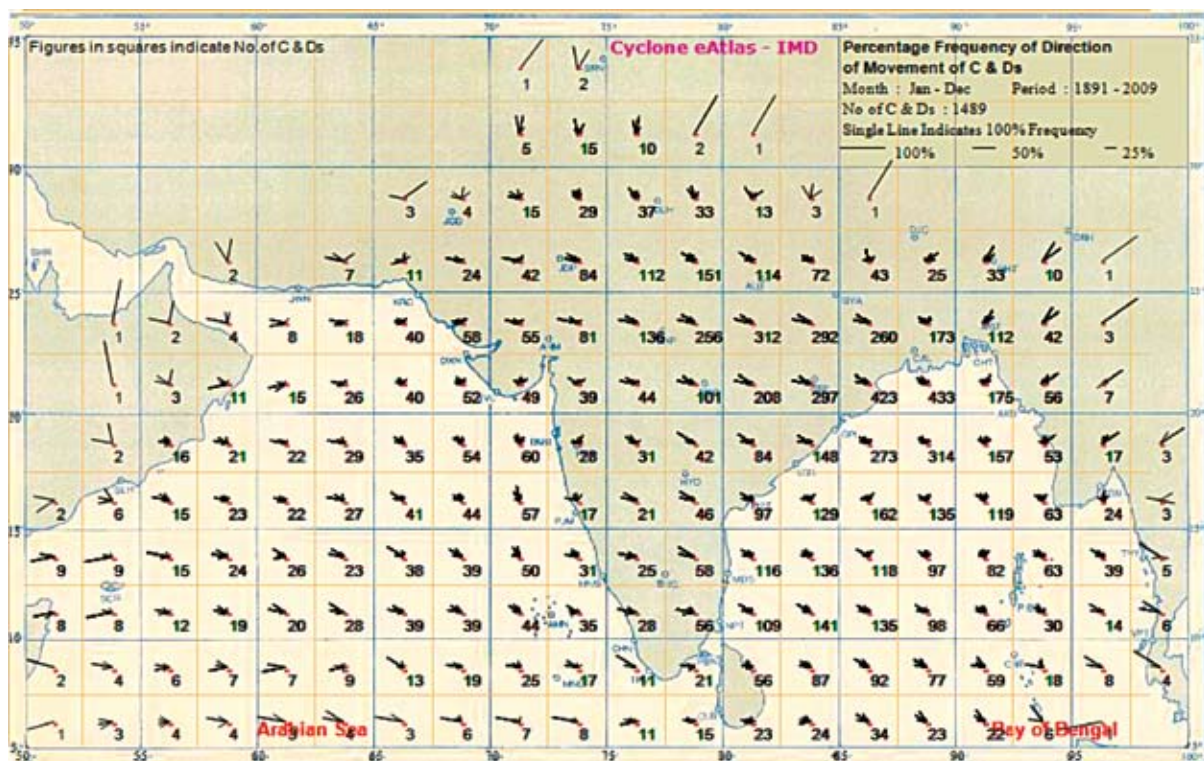

Fig. 1.14(b). Probability of direction of movement of cyclonic disturbances over the NIO

total cyclones developing over Arabian Sea cross Gujarat coast and 11% each cross Pakistan and Oman coasts.

The CDs mostly dissipate when they move over the land. Also, when a CD over the sea comes across the unfavourable conditions like colder SST and high vertical wind shear, it dissipates over the sea itself. The frequency of dissipation is significantly higher over the West Arabian Sea, mainly due to colder SST. There are also significant numbers of cases of dissipation along the east coast of India, Bangladesh and Myanmar coasts.

The climatology of cyclonic disturbances presented here is based on data available in e-Atlas published by IMD. The limitation and scope of this Atlas have been discussed also by IMD (2008). One of the important limitations is that it does not include the short lived disturbances (life period < 12 hours).

Further, the climatology depends on the monitoring capability to detect the disturbances. The monitoring system over the region has undergone several changes with augmentation of surface observatories, introduction of RS/RW observations during 1930's, use of

Fig. 1.15 (a). Frequency of cyclone/ severe cyclone over the Bay of Bengal landfalling over different coastal states during 1891-2007.

Fig. 1.15 (b). Frequency of cyclone/severe cyclone over the Arabian Sea landfalling over different coastal states during 1891-2007

satellite since 1960s and implementation of meteorological buoys since 1997. Hence all these facts should be taken into consideration while analyzing the climatological characteristics of cyclonic disturbances over the NIO.

1.7. Naming of Cyclones

The WMO/ESCAP Panel on Tropical Cyclones at its twenty-seventh Session held in 2000 in Muscat, Sultanate of Oman agreed in principle to assign names to the

Table 1.5. Naming of Tropical Cyclones

Panel Member	Column one		Column two		Column three		Column four	
	Names	Pron'	Names	Pron'	Names	Pron'	Names	Pron'
Bangladesh	Onil	Onil	Ogni	Og-ni	Nisha	Ni-sha	Giri	Gi-ri
India	Agni	Ag'ni	Akash	Aakaa'sh	Bijli	Bij'li	Jal	Jal
Maldives	Hibaru	--	Gonu	--	Aila	--	Keila	--
Myanmar	Pyarr	Pyarr	Yemyin	Ye-myin	Phyan	Phyan	Thane	Thane
Oman	Baaz	Ba-az	Sidr	Sidr'	Ward	War'd	Murjan	<i>Mur'jaan</i>
Pakistan	Fa-noos	Fanoos	Nargis	Nar gis	Laila	Lai la	Nilam	Ni lam
Sri Lanka	Mala	--	Rashmi	Rash'mi	Bandu	--	Mahasen	--
Thailand	Mukda	Muuk-dar	Khai Muk	Ki-muuk	Phet	Pet	Phailin	Pi-lin
Panel Member	Column five		Column six		Column seven		Column eight	
	Names	Pron'	Names	Pron'	Names	Pron'	Names	Pron'
Bangladesh	Helen	Helen	Chapala	Cho-po-la	Ockhi	Ok-khi	Fani	Foni
India	Lehar	Le'har	Megh	Me'gh	Sagar	Saa'gar	Vayu	Vaa'yu
Maldives	Madi	--	Roanu	--	Mekunu	--	Hikaa	--
Myanmar	Nanauk	Na-nauk	Kyant	Kyant	Daye	Da-ye	Kyarr	Kyarr
Oman	Hudhud	Hud'hud	Nada	N'nada	Luban	L'luban	Maha	M'maha
Pakistan	Nilofar	Ni lofar	Vardah	Var dah	Titli	Titli	Bulbul	Bul bul
Sri Lanka	Priya	--	Asiri	Aa'siri	Gigum	Gi'gum	Soba	--
Thailand	Komen	Goh-men	Mora	Moh-rar	<i>Phethai</i>	Pay-ti	Amphan	Um-pun

tropical cyclones in the Bay of Bengal and Arabian Sea. After long deliberations among the member countries, the naming of the tropical cyclones over NIO commenced from September 2004. RSMC, New Delhi is continuing the naming of Tropical Cyclones formed over NIO since October 2004. The first name was 'ONIL' which developed over the Arabian Sea (30 September to 03 October, 2004). According to approved principle, a list of 64 names in eight columns has been prepared. The name has been contributed by Panel members. The RSMC-tropical cyclones, New Delhi gives a tropical cyclone an identification name from the above name list. The Panel member's name is listed alphabetically country-wise in each column. The names are used sequentially column-wise. The first name starts from the first row of column one and continues sequentially to the last row in column eight. The identification system covers both the Arabian Sea and the Bay of Bengal. These lists are used sequentially, and they are not rotated every few years unlike the Atlantic and Eastern Pacific lists. Out of 64 approved names, 29 names have been utilized till the end of year 2011 (Table 1.5).

A system will be named as per the Table once it intensifies into a cyclonic storm. During the stage of depression and deep depression, it will be named as per the serial number of the system for a given Ocean basin (e.g. Bay of Bengal and Arabian Sea). Hence the first system forming over the Bay of Bengal (BOB)

and Arabian Sea (ARB) will be named as BOB/01 and ARB/01 respectively.

If public wants to suggest the name of a cyclone to be included in the list, the proposed name must meet some fundamental criteria. The name should be short and readily understood when broadcast. Further the names must not be culturally sensitive and not convey some unintended and potentially inflammatory meaning. A storm causes so much death and destruction that its name is considered for retirement and hence is not used repeatedly. The suggested name pertaining to India may be communicated to Director General of Meteorology, India Meteorological Department, Mausam Bhawan, Lodi Road, New Delhi-110003 for consideration.

1.8. Early Warning System

As tropical cyclone cannot be tamed to reduce their adverse effects, one has to learn to live with them. Effective Cyclone Disaster Prevention and Mitigation Plan requires:

- Hazard analysis
- Vulnerability analysis.
- Early Warning and Mitigation
- Community preparedness and planning at all levels to meet the exigencies.

Out of these early warning is a major component as evident from a survey conducted for the south Asian region.

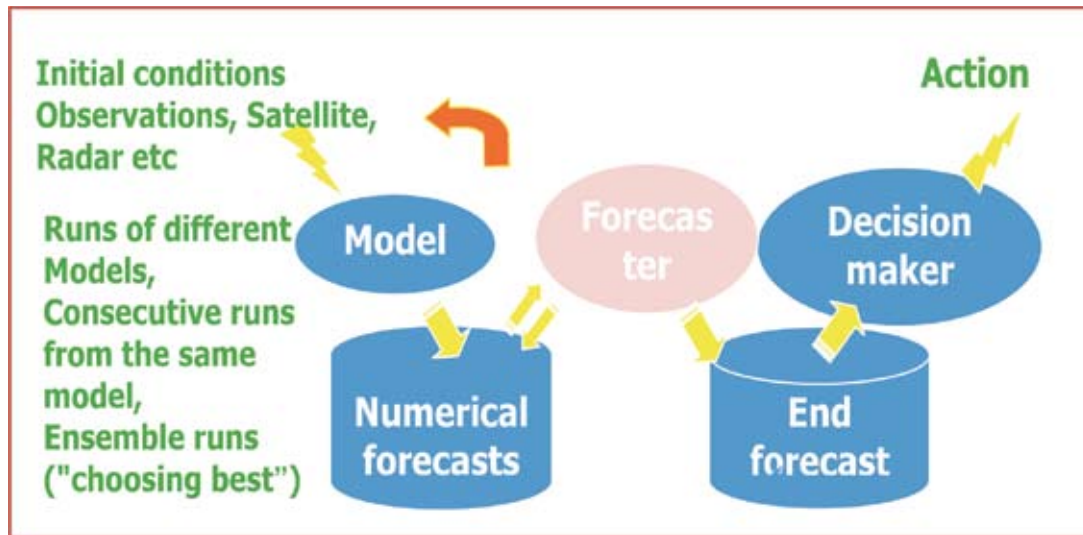

Fig. 1.16. Early Warning system of cyclone over NIO

Considering all the above, it is important to observe and understand the development of tropical disturbances for forecasting and warning the various user agencies and general public. India Meteorological Department (IMD) monitors and predicts CDs over NIO and provides early warning services for management of the cyclone. Various components of early warning system for a cyclone include (i) monitoring

and prediction, (ii) warning organization, (iii) warning generation, presentation & dissemination, (iv) coordination with disaster management agencies, (vii) public education & reaching out and (viii) post-event review. The entire early warning system of cyclone is depicted in Fig.1.16. All the above aspects of early warning system are discussed in the following Chapters.

2

Cyclone Warning Organisation

Cyclone warning is one of the most important functions of the India Meteorological Department and it was the first service undertaken by the Department as early as in 1865 and thus the service started before the establishment of the department in 1875.

2.1 Milestones

- 1864:** Two severe cyclonic storms in quick succession hit the east coast of India, causing enormous loss of human lives and property – the first one struck Kolkata in October and the second one struck Machilipatnam in November.
- 1865:** Concerned with these disasters, the Government appointed a committee in 1865 to formulate a scheme to develop a system of cyclone warnings. On the recommendations of the committee, Kolkata became the first port where a storm warning system was organised in the same year.
- 1880:** The storm warning scheme for west coast ports (Mumbai, Karachi, Ratnagiri, Vengurla, Karwar and Kumta) came into force.
- 1882:** The ports at Sagar Islands, Mud Port and Diamond Harbour were also included in the list of ports getting storm warning messages.
- 1886:** system of early warnings against cyclones was extended to cover all Indian ports.
- 1898:** Two different systems of storm warning signals (one for the east coast ports and another for west coast ports) were in use. A uniform system of storm warning signals was introduced at all the Indian ports. Kolkata office was responsible for issuing storm warning to all the ports (including those of Burma) around the Bay of Bengal, while the west coast ports were served by the Bombay Meteorological Reporter initially and later from Simla which was then the headquarters of the Department.
- 1928:** After the shift of the HQ of the Department from Simla to Pune in 1928, the storm warning work for west coast was done from Pune.
- 1945:** With the formation of Regional Meteorological Centres, the storm warning work for the Bay ports on the east coast from Kalingapatnam

- southwards was transferred to Chennai (Meenambakkam).
- 1947:** Responsibility for the Arabian Sea ports was taken over by the Meteorological Office at Santacruz (Mumbai).
- 1956:** As the combination of the meteorological activities for aviation and marine interests in the same office had some drawbacks, these two activities were bifurcated to achieve a more efficient functioning of the storm warning service. Separate storm warning centres came to be established at Colaba (Mumbai)
- 1969:** (i) Separate storm warning centres came to be established at Nungambakkam (Chennai).
- (ii) The responsibility for the ports on the west coast from Karwar southwards was also transferred from Mumbai to Chennai.
- (iii) Government of India appointed a committee called the Cyclone Distress Mitigation committee (CDMC) for Andhra Pradesh to examine various measures to mitigate human suffering and reduce loss of life and property due to cyclonic storms. Subsequently similar committees were set up for Odisha and West Bengal.
- 1971:** CDMC for Andhra Pradesh recommended IMD to establish storm warning centre at Visakhapatnam for issuing cyclone warnings to coastal Andhra Pradesh.
- 1972:** CDMC for Odisha recommended IMD to establish storm warning centre at Bhubaneswar for issuing cyclone warnings to coastal Odisha.
- 1973:** (i) Storm warning centre was set up at Bhubaneswar for catering to the needs of Odisha.
- (ii) Regional Meteorological Centre (RMC) for Tropical Cyclones, New Delhi came into existence with the formation of WMO/ ESCAP Panel.
- 1974:** Storm warning centre was set up at Visakhapatnam for catering to the needs of Andhra Pradesh.
- 1988 :** (i) In pursuance of the recommendation of Cyclone Review Committee, Storm Warning Centre was established at Ahmedabad for catering the needs of Gujarat, Union Territory of Diu, Daman, Dadra and Nagar Haveli.
- (ii) Regional Meteorological Centre (RMC) New Delhi was redesignated as Regional Specialized Meteorological Centre (RSMC) Tropical Cyclones, New Delhi with effect

from 1st July 1988 and assigned the responsibility of issuing Tropical Weather Outlooks and Tropical Cyclone Advisories for the benefit of the countries in the WMO/ESCAP Panel region bordering the Bay of Bengal and the Arabian Sea, namely, Bangladesh, Maldives, Myanmar, Oman, Pakistan, Sri Lanka and Thailand.

1990 : (i) As per one of the recommendations of the Cyclone Review Committee (CRC), a Cyclone Warning Directorate was established in 1990 in the Office of the Director General of Meteorology, New Delhi to co-ordinate the cyclone warning work in the country in totality.

(ii) Establishment of Cyclone Warning Research Centre at Regional Meteorological Centre, Chennai to carry out research as per operational requirement

2003 : Cyclone Warning Division acted as Tropical Cyclone Advisory Centre (TCAC), New Delhi as per the requirement of International Civil Aviation Organisation (ICAO)

2.2. Organizational Structure

At present, the cyclone warning organization of the India Meteorological Department (IMD) has three-tier system to cater to the

needs of the maritime states. There are Area Cyclone Warning Centres (ACWCs) at Chennai, Mumbai and Kolkata and Cyclone Warning Centre (CWCs) at Visakhapatnam, Ahmedabad and Bhubaneswar. The co-ordination of cyclone warning operations at the national level is done by the “Weather Central” at Pune whereas the international coordination and liaison with the Central Government organizations and other agencies as well as co-ordination and supervision of cyclone warning activities are done by Cyclone Warning Division (CWD) at New Delhi. CWD, New Delhi is also functioning as Regional Specialised Meteorological Centre - Tropical Cyclones (RSMC - Tropical Cyclones), New Delhi.

2.2.1. Regional Specialized Meteorological Centre (RSMC)- Tropical Cyclones, New Delhi

There are five tropical cyclones regional bodies, i.e. ESCAP/WMO Typhoon Committee, WMO/ESCAP Panel on Tropical Cyclones, RA I Tropical Cyclone Committee, RA IV Hurricane Committee, and RA V Tropical Cyclone Committee. Under these regional bodies, there are six RSMCs as shown in Fig.2.1. The areas of responsibility of different RSMCs are shown in Fig.2.1. The RSMC is responsible for monitoring and prediction of tropical cyclones over their respective regions.

The area of responsibility of RSMC- New Delhi covers Sea areas of north Indian Ocean north of equator between 45° E

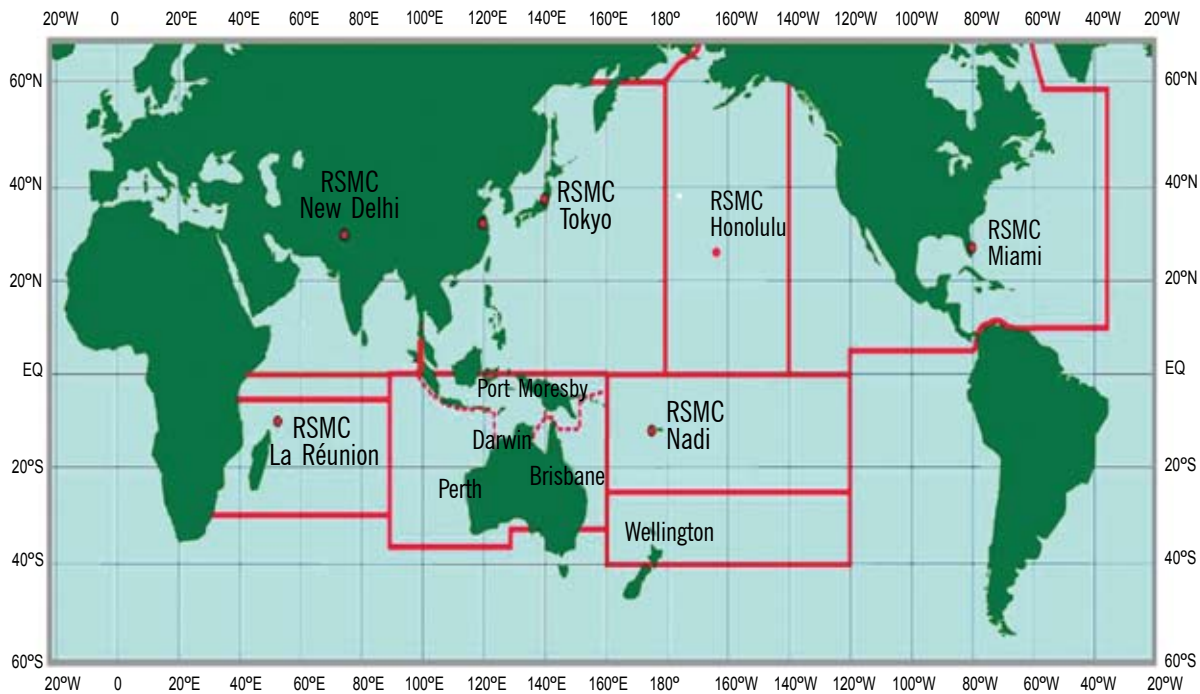

Fig. 2.1. Area of responsibility of different RSMCs and TCWCs

and 100° E and includes the member countries of WMO/ESCAP Panel on Tropical Cyclones viz, Bangladesh, India,

Maldives, Myanmar, Pakistan, Sri Lanka, Sultanate of Oman and Thailand as shown in Fig.2.2

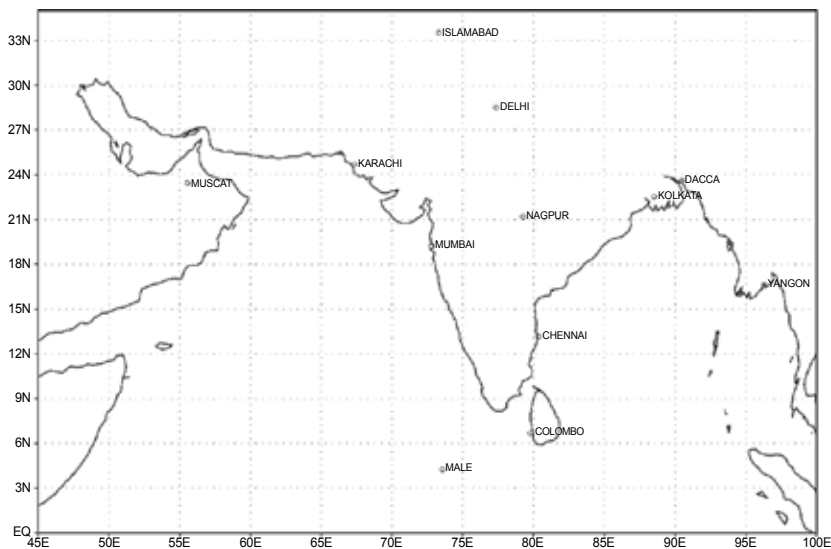

Fig. 2.2. Area of responsibility of RSMC- Tropical Cyclones, New Delhi

2.2.2. Cyclone Warning Division

As per one of the recommendations of the Cyclone Review Committee (CRC), a Cyclone Warning Directorate co-located with RSMC Tropical Cyclones New Delhi was established in 1990 in the Office of the Director General of Meteorology, New Delhi to co-ordinate the cyclone warning work in the country in totality.

2.2.3. ACWCs/CWCs

With the establishment of the additional Centres at Bhubaneshwar and

Visakhapatnam, the Storm Warning Centres at Kolkata, Chennai and Mumbai were named as *Area Cyclone Warning Centres* (ACWC) and the Storm Warning Centres at Visakhapatnam, Bhubaneshwar and Ahmedabad as *Cyclone Warning Centres* (CWC). CWCs Visakhapatnam, Bhubaneshwar and Ahmedabad function under the control of the ACWCs-Chennai, Kolkata and Mumbai respectively (Fig.2.3 & Table 2.1). M.C. Hyderabad liaises between CWC Visakhapatnam and Andhra Pradesh Government officials; warnings issued by CWC Visakhapatnam are sent

Fig. 2.3. Cyclone Warning Organisational Structure of IMD

Table 2.1. Area of Responsibility of ACWC/CWC

Centre	Area of Responsibility		Maritime State
	Sea area	# Coastal area	
ACWC Kolkata	Bay of Bengal	West Bengal, Andaman & Nicobar Islands.	West Bengal & Andaman & Nicobar Islands.
ACWC Chennai		Tamil Nadu, Pondicherry, Kerala & Karnataka	Tamil Nadu, Puducherry, Kerala, Karnataka & Lakshadweep.
ACWC Mumbai	Arabian Sea	Maharashtra, Goa	Maharashtra, Goa.
CWC Bhubaneswar	-	Odisha	Odisha
CWC Visakhapatnam	-	Andhra Pradesh	Andhra Pradesh
CWC Ahmedabad	-	Gujarat, Diu, Daman, Dadra & Nagar Haveli	Gujarat, Diu, Daman, Dadra & Nagar Haveli

Coastal strip of responsibility extends upto 75 km. from the coast line.

to M. C. Hyderabad also for briefing the Andhra Pradesh Government officials at the State Capital.

The present organisational structure for cyclone warnings is a three-tier one, with the ACWCs/CWCs actually performing the operational work of issuing the bulletins and warnings to the various user interests, while the CWD New Delhi and the Deputy Director General of Meteorology (Weather Forecasting), through Weather Central, Pune coordinates and guide the work of the ACWCs/CWCs, exercise supervision over their work and takes necessary measures for continued improvement and efficiency of the storm warnings system of the country as a whole. The ultimate responsibility for operational storm warning work for the

respective areas however, rests with the ACWCs and CWCs.

2.2.4. Other offices

The co-ordination of the cyclone warning work is done through exchange of bulletins and personal discussions, internet, mobile and STD calls and fax messages between O/o DDGM(WF) Pune - Weather Central, Cyclone Warning Division, New Delhi and concerned ACWCs/CWCs on days of disturbed weather over the sea areas. In addition, on occasions of cyclonic storms affecting the coastal areas, the weather bulletins issued by the ACWCs/CWCs for inclusion in the All India Radio (A.I.R) news cycles are consolidated and edited by O/o DDGM(WF) Pune - Weather Central,

before they are passed on to AIR New Delhi through NWFC, New Delhi.

The storm warning work at the ACWCs/CWCs is supervised by DDGM(WF) through a scrutiny of the warnings issued for their adequacy and timeliness and remedial action is advised whenever necessary. To improve the service and to bring about uniformity of practices, forecasting circulars and technical instructions are issued from time to time by O/o DDGM(WF) Pune. O/o DDGM (WF) Pune also arranges Annual Cyclone Review meetings for an appraisal of the action taken during the cyclones of the previous years as postmortem examination of this nature

is of considerable benefit to operational forecasters. This enables them to correct past mistakes, if any, and to improve the performance in future.

DDGM (Satellite Meteorology) prepares satellite account on cyclones within one month and sends to O/o DDGM (WF) Pune. The Annual storm accounts and other reports regarding cyclones for supply to national and international agencies are prepared at CWD, New Delhi and O/o DDGM(WF), Pune. Cyclone Warning Research Centre (CWRC) at Chennai has the responsibility to carry out the research required for improvement of cyclone warning in the country.

3

Needs for Monitoring and Prediction

3.1. Data and Products

The following inputs are needed for monitoring and prediction of cyclonic disturbances over the north Indian Ocean

❖ **Surface observational data and synoptic analysis products**

- Real time AWS/ARG data, Conventional Synoptic Observations, Coastal hourly observations, High Wind Speed Recorders (HWSR), ship and buoy data.
- Three hourly synoptic analysis charts

❖ **Upper air observational data and analysis products**

- Real time observation from pilot balloon and RS/RW or GPS sonde
- Upper air analysis charts
- Tephigrams

❖ **Satellite products from IMD and international centres**

Visible imagery

- Tracking (locating the centre)
- Intensity analysis by Dvorak Technique

Infra-Red imagery

- Tracking (locating the centre)
- Structure analysis
- Intensity analysis by Dvorak technique

Water Vapour imagery

- Synoptic assessment of the storm environment)

Micro-wave imagery

- Microwave (MW) Radiometer estimates of the following Parameters from Brightness Temperature (TB)
- Rain rate, total precipitable water (TPW), surface wind speed, sea surface temperature (SST), Salinity etc
- Estimates of Sea Surface Wind through backscattering based on MW Scatterometer
- Estimates of rain rate from backscattering of raindrops based on MW Rain Radar
- Estimates of Temperature/Moisture Profile based on MW Sounder
(Source: http://www.nrlmry.navy.mil/tc_pages/tc_home.html)

Bulletins

- Satellite fix (IMD and other centres)
- Cloud top temperature
- Special cyclone bulletin

❖ **Radar data and products**

- i. Maximum reflectivity (Max (Z))
- ii. Plan Position Indicator (PPI(Z))
- iii. Volume velocity processing (VVP(Z))
- iv. PPI (V)
- v. Surface rainfall intensity (SRI)
- vi. 24 hours Precipitation accumulation at 0300 UTC
- vii. Track prediction products
- viii. Uniform Wind Technique (UWT)
- ix. Full resolution imagery of PPI(Z)/Max(Z)
- x. Hourly radar bulletin

❖ **Dynamical and statistical Model products from various national and international centres**

NWP division makes the arrangement to provide all NWP model products and derived products. Additionally the NWP model products are also obtained from NCMRWF, IIT Delhi, Indian Air Force (IAF) etc.

❖ **Useful web sites for TC forecasting**

		w.Storm Surge model (IITD)	CWD, IIT Delhi

3.2. Intensive Observational Phases (IOP)

- IOP should be declared from the stage of depression if it has potential to intensify into a cyclone. CWD will take the decision and necessary action will be taken by concerned ACWC/CWC.
- During IOP, concerned RMC/MC should make the arrangement to send the persons at every 50 km along with full equipment in the disturbed area to take the observations and transmit them.
- All the RMC/MC will assure that there should be AWS at every 50 km in the coastal areas under their territory.
- Hourly observations should be started immediately during IOP in the respective areas of RMC/MC and should reach at CWD by email otherwise by fax or telephone in addition to GTS communication.
- **AWS:** DDGM(SI), Pune will ensure the real time transmission of data from AWS stations to DDGM(Telecom) Delhi in GTS mobile synop format.
- **Synoptic observations:** Synoptic observatories of IMD network of costal stations shall report data on hourly basis, during IOP. During normal period 3 hrly SYNOP will be collected. RSMC, New Delhi will write to concerned WMO/ESCAP Panel member countries to ensure the availability of synoptic data from respective region for the IOP period.
- **Buoys:** Real-time collection of hourly data from deep Ocean and met-ocean buoy network over the Bay of Bengal from INCOIS Server will be made by Telecom Division.
- **Upper air:**
 - Upper air RS/RW data from IMD stations in coastal areas will be collected 12 hourly for normal days. However, during the IOP phase, 6 hourly data shall be collected. The

flight terminating below 200 hPa are to be repeated.

- Due arrangements to receive all available Pilot Balloon data sets (twice daily) from the IAF will be made by Telecom Division
 - Wind profiler support from the existing Gadanki and SHAR is to be activated so as to receive hourly profiles in the lower troposphere. CWD will request Director NARL Gadanki and Met I/C SHAR with copy to Principal Scientist, ISRO for organizing necessary observational support during IOP.
- **DWR** : DWR support from various coastal Radars with uniform storm scanning strategy will be ensured prior to the cyclone season.
- **NWP** : It shall make all necessary arrangements for the generation of global and regional analysis fields data at 4 analysis times (00, 06, 12, 18 UTC) during IOP. Efforts will be made to bring out the Model forecast within three hours of the observation time.
- **Coordination with International Agencies**: Director RSMC, New Delhi shall request the WMO/ESCAP Panel

countries about the IOP and solicit their cooperation in the real time exchange of data (surface, upper air and special observations) for their utilization in the generation of most representative meso-scale analysis fields for generating improved quality of track, intensity and landfall of tropical cyclones.

3.3. Manpower Needed

Following manpower is needed during IOP along with the supporting staff.

- **CWD, New Delhi**: Two Group A officers will work round the clock.
- **Satmet Division, New Delhi**: One Group A officer will work round the clock.
- **Radar Division, New Delhi**: One Group A officer will work round the clock.
- **NWP Division, New Delhi**: One Group A officer will work round the clock.
- **ACWC/CWC**: One Group A officer will work round the clock
- **CDR/DWR Station**: One Group A officer will work around the clock

4

Observational Aspects of Cyclone Warning System

4.1. Introduction

Observational network for cyclone forecasting is aimed at continuous monitoring of the horizontal and vertical structure of the atmosphere. Surface and upper air observations from various oceanic and land platforms are the basic data required by a cyclone forecaster. The latest technological advances like Satellites, Radar and computers provide invaluable support to the cyclone warning system, complementing the conventional observing system. The observational aspects of cyclone warning system include different

types of observations (Fig. 4.1a-b).

The types of observations relevant to storm warning work are:

A. Surface observations from:

- i) Land synoptic stations
- ii) Ships
- iii) Buoys
- iv) Tide gauges
- v) Aviation meteorological offices
- vi) Automatic Weather Stations (AWSs)

Broad Classification of Observations

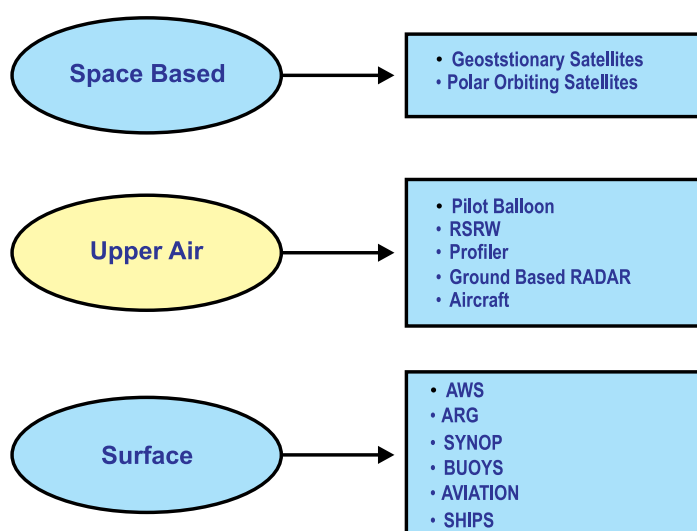

Fig. 4.1(a). Classification of observations

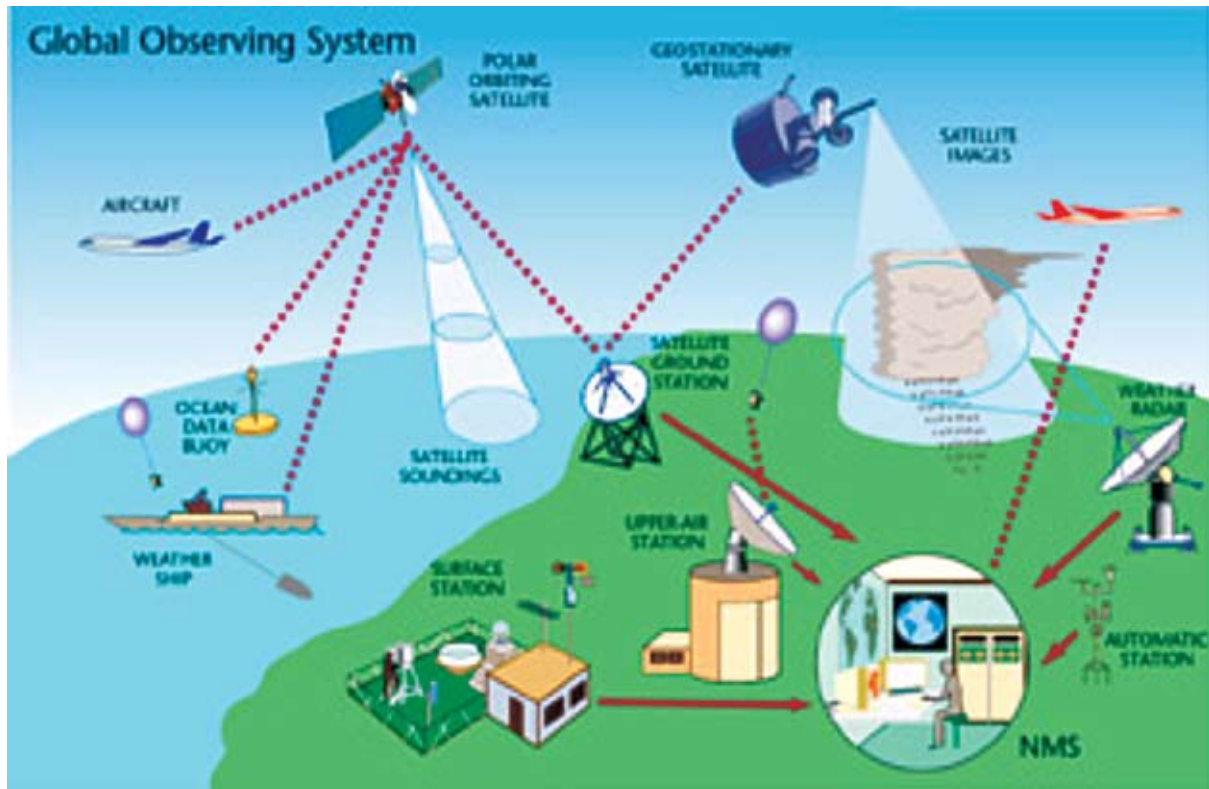

Fig. 4.1(b). Observational network for cyclone monitoring

B. Upper air observations from:

- (i) Pilot balloon stations
- (ii) GPS Sonde/ Radiosonde /Radiowind stations
- (iii) Wind profiler stations

C. Radar Observations

D. Satellite observations

E. Aircraft observations

F. Microseism observations.

Each of the above observational systems is discussed in detail in the following sections.

4.2. Surface (Land, Ocean) Based Observations

Surface data is the foundation over which the edifice of synoptic meteorology is built. Their horizontal coverage is generally good over populated land, and marginal to poor over oceanic or desert areas, although oceanic buoys and AWSs are being deployed and installed in large numbers and the situation has improved to a great extent in recent period.

Over land surface, data from an increasing number of AWSs contain information on wind, temperature, moisture and mean sea level pressure, with weather elements

such as cloud cover or visibility mostly available from manned and aeronautical stations. Regional efforts are underway to collect, standardise and have quality control of data from observing networks from non-departmental government and non-government agencies.

Over the oceans, winds, SST and MSLP, measured on ships, buoys and island stations are important parameters used in cyclone forecasting. Even very isolated stations may play an important role in cyclone forecasting, especially when their input is used for NWP model output.

Apart from the surface observations of Voluntary Observing Fleet (VOF) ships, Array of buoys and tide gauge network form an integral part of ocean observing system. According to recent WMO report, 1250 surface drifting buoys are deployed. 6700 ships have been registered world wide, yet less than 2300 ships report regularly. Observations from buoys and ships are vital indeed in estimation of position, intensity and track of cyclones and all efforts should be made to maximise the reception of ships' data.

4.2.1. Land Based Conventional Surface Observatories

There are at present 559 surface observatories in India for recording meteorological parameters such as surface air pressure, temperature, humidity, wind, clouds, visibility and rainfall etc. Appendix-4.1 & 4.2 give the list of all the

coastal and island observatories of India and in neighbouring countries. IMD has classified the observatories as class I to Class VI, depending upon the Observatory setup and its purpose. The coastal observatories mentioned in the table are mostly Class I and Class II observatories. The corresponding WMO classification for Class I observatories are Principal Climate Observatories with 3 to 8 observations per day. It should have three autographic charts and should take observations for pressure, temperature, wind and rainfall. Class II observatories should take and communicate 2 sets of observations per day. Class V stations measure precipitation only and WMO has classified them as Precipitation stations.

In addition, the acquisition of surface data from the departmental and part time observatories, rainfall data from stations under District-wise rainfall monitoring scheme (DRMS), Intensive Agricultural Development Programme (IADP) and All India General Scheme (AIGS) form an integral part of the cyclone warning observational network. As most of the stations in DRMS, IADP and AIGS function under the respective state governments, effective interaction with the concerned agencies is essential for maximising reception of real time data from these stations. During 2007 Tamil Nadu government and IMD signed an MOU for exchange of rainfall data in real time. Similar arrangements in other coastal states are desirable.

Proposed installation of AWS by various agencies of the Central and State governments along the coast is expected to give the required density to locate sub-synoptic scale systems.

4.2.2 Cooperative Cyclone Reporting Network of Stations

As the regular coastal network is not dense enough to discern cyclonic storms of smaller dimensions, Co-operative Cyclone Reporting network of stations have been started along the coast on the recommendations of Cyclone Distress Mitigation committees (CDMCs). In Andhra Pradesh, there are 13 Cooperative Cyclone Reporting stations while Odisha state has 16 CDMC stations. The list of such CDMC stations is given in Appendix-4.3. These are all police stations and they collect rainfall and wind data and the information is passed on to IMD office through police wireless network and telephone. In most of these centres, it has been proposed to set up either AWS or telemetric rain gauge. The Cooperative network of observatories in the state of Andhra Pradesh will send the information to Cyclone Warning Centre at Vishakapatnam through Phone/e-mail/Police Wireless. These stations record only 03 and 12UTC observations during cyclone season and only 03UTC during non-cyclone season. Hourly observations can be obtained from these stations during cyclone situations. The reports are in plain language. There is a proposal by the

concerned CDMC authorities to convert the 16 CDMC stations in Odisha into AWS stations.

In Maharashtra State, a special wireless network between IMD, Revenue Secretary, Mantralaya, Director of fisheries, police control room and collector's office is functioning during monsoon season. This network should be activated during cyclone situations by appropriate liaison with the Chief Secretary's Office. Similarly, there is wireless connectivity between CWC Bhubaneswar and Odisha State Control Room.

4.2.3. Time of Observations

The standard time for all observations is UTC. WMO recommendations state that the observation should be made in as short a time as possible just prior to the nominal time of observation. These observations are typically started by (HH-10) and pressure reading is taken last at the exact hour. The observation is to be transmitted before the hour is complete. As per national practice, 03 and 12UTC observations report Minimum and Maximum temperatures recorded on that day and 03UTC report also includes 24 hours total rainfall. Synoptic observation is the coded synoptic summary of the current weather at each of the large number of synoptic stations. These observations when plotted on a chart give the complete picture of the atmosphere as though from a bird's eye view and hence the word 'synoptic'

is used to describe these simultaneous observations. The observations taken at 00, 06, 12 and 18 UTC are called main synoptic observations and those taken at 03, 09, 15 and 21 are called auxiliary synoptic observation.

4.3. Ship Observations

International Meteorological Organisation, the predecessor of World Meteorological Organisation was primarily started to serve the Marine community. Before the advent of satellite, ships observations were the major source for locating cyclones. Observations from ships provide vital data about disturbances over sea areas. Though land stations along the coast supply much valuable information as the storm approaches the coast, ships reports from the cyclone field form the main source of conventional observations while the storm is still out at sea. Even with the advent of radars and satellites, ships observations are still very vital in cyclone forecasting.

4.3.1 Voluntary Observing Fleet (VOF)

The number of ships under Voluntary Observing Fleet is 203. It has merchant's ships of Indian as well as foreign ships and ships belonging to Indian navy. These ships are equipped with instruments to record meteorological parameters and some of the crew on board are trained in taking and recording the observations. These ships are categorised as selected

ships, supplementary ships and auxiliary ships. Selected ships are equipped with sufficient certified meteorological instruments for making observations and report in the full SHIP code form (WMO FM 21V). In addition, these observations are recorded in the meteorological logbooks. The supplementary ships are equipped with limited number of certified meteorological instruments for making observations and they transmit reports in abbreviated code form (WMO SHIP Code Fm.22V). The observations are recorded in the meteorological logbooks. The auxiliary ships are normally without certified meteorological instruments and they transmit reports in reduced code form (WMO SHARED FM.23V) or in plain language during disturbed condition. The WMO publication International List of Selected, Supplementary and Auxiliary ships (WMO No.47 T.P 18) which gives information about all voluntary observing ships including the equipments on board and the call sign (Alpha numeric characters for ships identification) should be kept in all forecasting offices.

4.3.2. Recording and Reporting of Ship Observations

Observations are taken both at main standard times (00, 06, 12 and 18 UTC) and supplementary observations (03, 09, 15 and 21 UTC) subject to non-interference in their navigational duties. Additional observations should be taken during sudden and dangerous weather

Fig. 4.2. Picture of a Data Buoy deployed at Sea

developments and transmitted immediately, regardless of standard time.

4.4. Data Buoy Network

Department of Ocean Development, Government of India has established the National Data Buoy Programme (NDBP) in 1997 at National Institute of Ocean Technology (NIOT) Chennai. A network of fourteen data buoys (Table 4.1.) has been established both in Arabian Sea and Bay of Bengal during the implementation period of 1997-2002, which has subsequently been increased to twenty-five and poised for further growth.

The moored data buoys are floating platforms, which carry sensors to measure

Table 4.1. List of active buoys

Basin	Buoy ID	Latitude	Longitude
Arabian sea	AD02	15.0	69.0
	AD03	12.0	69.0
	AD04	8.5	73.0
	AD05	10.5	72.3
	SW02	17.4	70.7
Bay of Bengal	BD02	18.0	90.0
	BD07	6.2	85.9
	BD08	18.2	89.7
	BD10	16.5	88.0
	BD11	14.2	82.9
	BD12	14.5	94.0
	BD13	11.0	86.5
Andaman	CB01	11.6	92.6
Lakshadweep	CB02	10.9	72.2

CB: Coastal buoy, SW: Shallow water buoy, AD: Arabian sea data buoy, BD: Bay of Bengal data buoy

Wind Speed & Direction, Atmospheric Pressure, Air Temperature, Humidity, Conductivity, Sea Surface Temperature, Current Speed & Direction and Wave Parameters. The wave parameters that are measured include significant wave height, average wave period, average wave direction, Swell wave height and Swell wave period. Maximum wave height and Period of the highest Wave are also measured. The buoys are equipped with global positioning system, beacon light & satellite transceiver. They have solar panels to charge the battery pack during daytime. The recorded observations are collected by Indian National Centre for Ocean Information Services (INCOIS), Hyderabad and sent as email to the forecasting offices apart from GTS transmission through IMD.

4.5. Tide Gauges

Tide gauges (Fig.4.3) have been installed at Chennai, Cochin, Tuticorin, Mangalore and Port Blair along the Indian Coasts. Under the Tsunami Observation Network Programme, the network is expanded further at Vizhinjam, Kavaratti, Nagapattinam, Haldia and Kakinada. All the tide gauges are linked with satellite and online data reception at NIOT is established with password protection. These tide gauges would give vital information about the tidal and swell waves.

4.6. Reports from Airport Meteorological Offices

Airport Meteorological Offices record half hourly/hourly meteorological reports and they are known by their acronym METAR. Those airports having round the clock air traffic control watch prepare reports at half hourly interval. In other airports they prepare half hourly reports during watch hours and hourly reports during other periods. In the event of occurrence of significant changes in wind, visibility, cloud and weather, special reports are prepared and are known as SPECI. These Meteorological reports would supplement the data already obtained from other sources. Aircrafts during flight, report wind and temperature at the cruising level at certain places designated as meteorological reporting points. These observations known as AIREPS/PIREPS are transmitted by High Frequency Radio Transmission (HFRT) to communication unit of Airport Authority for onward transmission to airport meteorological office. Sometimes, landing pilots debrief the airport meteorological office. In vast data sparse ocean areas, these observations are invaluable. These data are plotted in the appropriate upper level chart (depending upon the cruise level).

Fig. 4.3 (a-b). Schematic acoustic tide gauge and Tide Gauge Network in India

4.7. Special Observations from Coastal Stations

4.7.1. Need for Special Observations

Except for 03 and 12 UTC charts, the network of coastal observations at the other hours is not sufficient for cyclone warning work. During periods of disturbed weather out at sea, observations from all the coastal and island observatories may be required at synoptic hours other than 03 and 12 UTC also. Therefore, it will be necessary to call for special observations on such occasions from observatories at some of the synoptic hours at which they may not take routine observations. Requisitions for special observations can be sent both by ACWCs & CWCs. Sometimes hourly observations are also required.

4.7.2. General Instructions

The following are the general instructions for calling special observations from surface observatories:

Special observations are to be called from coastal and island stations for the preparation of 3 hourly synoptic charts (00, 03, 06, 09, 12, 15 and 21 UTC) from the depression stage onwards or even when a depression is expected to form for the preparation of special charts for the issue of three hourly bulletins.

When landfall is expected within 48 hrs

However, if a cyclonic storm is within striking distance from the coast and the landfall is expected within the next 48 hrs, hourly special observations may be called from a restricted coastal area towards which the storm is heading, for determining the position of the storm, its intensity as well the place and time of landfall etc., from the sequence of hourly changes at these coastal stations. The usefulness of these observations is given with an illustration in the next section. These messages are cryptic coded messages giving date, time, cloud cover, wind speed & direction and

Time (UTC)→ Station ↓	1200	1300	1400	1500	1600	1700	1800	1900	2000	2100
Kakinada (43189)										
Machilipatnam (43185)										
Bapatla (43189)										

Fig. 4.4. Typical coastal observations taken during cyclone monitoring

mean sea level pressure. They also include rainfall and pressure change during past 24 hours if available. The message does have the provision of indicating the wind speed in plain text if it exceeds 20 Knots. These messages are obtained at present through HFRT (High Frequency Radio Telephony), E-mail, Automatic message switching systems and through telephone.

4.7.3. Discretion of Storm Warning Officer

It is left to the discretion of the Storm Warning Officer to decide how frequently the special observations are to be called. He should consider each case on its merits.

4.7.4. Role of Special Observations in Determining the Period of Landfall

Special observations (Fig.4.4) are coastal observations from Indian stations reported at one-hour interval. The code used for the observations is YYGG Nddff pppWW 4RRP₂₄ P₂₄. The symbols have the usual meaning. In order to show the importance of these observations the special observations of three stations viz., Kakinada, Machilipatnam and Bapatla are plotted for the period 12UTC to 21UTC of 16th December 2003. The time of landfall could be discerned to be around 18UTC near Machilipatnam. The veering of wind at Machilipatnam and backing of winds at Bapatla reveals movement of the

system between these two stations. The southeasterly winds at 19UTC indicate that system has entered the land. The highest value of 24 hours Pressure change also occurred in this period and clearly shows that landfall has occurred around this period.

4.7.5 Importance of 24 hr Pressure Change (P_{24} P₂₄)

In the previous section the importance of P_{24} P₂₄ observation is amply illustrated in determining the land fall period. In this section the importance of Isallobars is given. Lines passing through areas of equal pressure changes are known as Isallobars. An Isallobaric low is as good as a pressure low. The area of highest pressure fall (Isallobaric low) indicates the direction in which the system is heading. So Isallobars play a major role in prognosis of cyclone movement.

4.7.6. Discontinuance of Special Observations

After the system has crossed coast and special observations are no longer needed, the observatories concerned should be informed immediately to discontinue the special observations. Special care should be taken to see that the observations are not received after instructions to discontinue them have been issued. Further messages to stop the observations have to be issued to such observatories which still continue to send the special observations.

4.8. Automatic Weather Stations

Presently, about 675 Automatic Weather Stations (AWS) are located all over India. Data are being received at the Central Earth Receiving station located at Pune. In addition, 1350 Automatic Rain gauge stations (ARG's) are also planned. 500 ARG's will have sensors for air temperatures, relative humidity and rainfall. The remaining 850 ARG's will have only rainfall sensors. Out of 1350, about 450 AWSs have been installed till the end of 2011.

AWSs (Fig.4.5) use state-of-art data logger and transmitter with sensors interfaced for data sampling and recording.

Meteorological sensors for Air Temperature, Relative Humidity, Atmospheric Pressure, Rainfall, Wind Speed and Wind Direction are interfaced with both Sutron and Astra make AWS. Apart from these parameters, at few selected Sutron-make AWSs have additional sensors for Global Solar Radiation, Soil Temperature and Soil Moisture.

AWS transmit data in UHF frequency 402.75 MHz, every hour in their allocated time slots which are received by the Data Relay Transponder of the geostationary satellite Kalpana-1 and are retransmitted by the satellite at a downlink frequency of 4506.05 MHz to the Central Receiving Earth Station located at Pashan, Pune. The technique utilized for transmission is

Fig. 4.5. Schematic diagram of an AWS

called Pseudo-Random Burst Technique (PRBS) where a defined number of AWS transmit three times in a 10-minute window allocated to them.

The raw data received from all AWS is processed at the Earth Station and the synoptic data in WMO Synop Mobile FM-14 Ext format is transmitted to AMSS Mumbai via ftp through 64 kbps leased line which is then put to the Global Telecommunication System (GTS) by AMSS Mumbai every hour. The processed data is archived at Earth Station, Pune. Synoptic charts plotted in synergie system using data from AWS are available for forecasters

4.9. Upper Air Observations

Wind and temperature data of the upper atmosphere is collected by using Pilot balloons and Radiosonde/Radiowind.

4.9.1. Pilot Balloon Observatories

Meteorological conditions in the upper air have an important bearing on the expected weather. Observations for measurement of wind speed and direction alone are made 2 to 4 times a day at Pilot Balloon Observatories (PBO), which use optical theodolites. Upper wind measurements made at PBO are limited to a few km heights.

These observations are vital in determining whether the system would dissipate due to entrainment of dry land air, in locating the ridge and to know about the

steering currents for determining Cyclone movement. But in overcast Sky conditions with low clouds, it may not be possible to take the observation as the balloon may disappear in the cloud. In that situation Radiosonde/ Radiowind provide the upper air data. There are 62 pilot balloon observatories spread all over the country (Fig.4.6). WMO has established standard times for conducting upper air observations and the four synoptic hours of 00, 06, 12 and 18 UTC are the designated hours. Most balloons are released actually 30 to 45 minutes before these times and the scheduled observation period coincides with the middle of the observation. If only two observations are taken, it is taken at 00 and 12UTC. Under international practice, if only one observation is taken, it is taken at 00 or 12 UTC, whichever is closest to the local sunrise time.

4.9.2. Radiosonde/Radiowind Observations

Radiosondes serve as main observing system for determination of detailed vertical structure of the atmosphere. This is due to their excellent vertical resolution (provided full resolution data are being transmitted instead of standard/significant level data only). Vertical stability analyses which require data in great details are not necessarily captured by NWP models; but can be obtained from, radiosonde data. Moreover, radiosonde data are very essential in NWP analyses and model assessment. Radiosondes are of primary

Fig. 4.6. Pilot balloon observatory network of India

importance in synoptic forecasting also for identifying the position of the ridge, steering current and thermal advection

IMD is at present using GPS sonde at 11 places and Mark IV radiosonde in other 28 places of its upper air network (Fig. 4.7). The computation is fully automated with a data resolution of two seconds. Usually 00 and 12 UTC observations are taken. For 06 and 18 UTC observations,

Pilot balloons are used. When a cyclonic storm is coming closer, taking Pilot balloon observations may be difficult. In that event special Radio sonde/Radar wind observations are taken.

4.9.3. Wind Profilers

Under modernization plan (Phase-I) of IMD, four nos. of wind profilers are likely to be installed in IMD's upper air

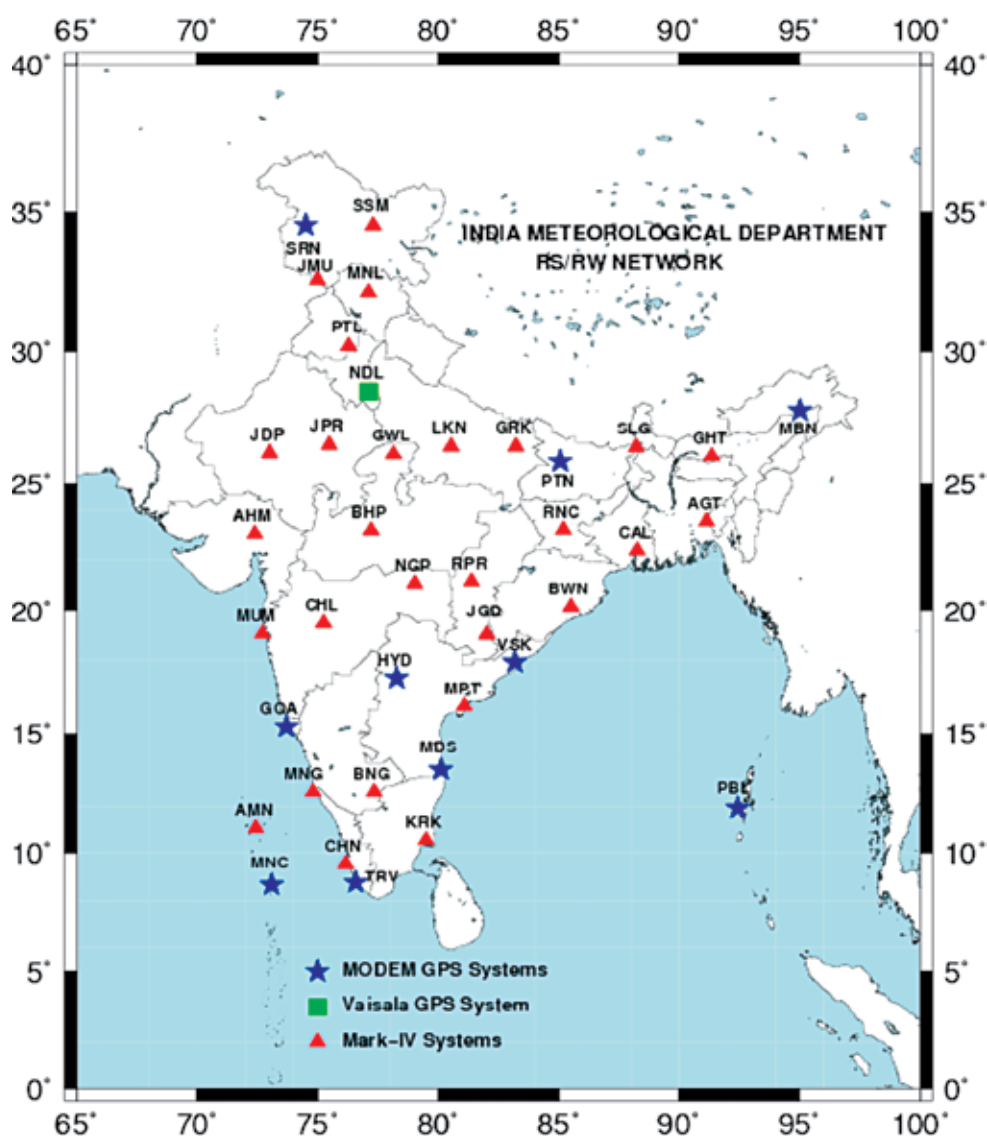

Fig. 4.7. RS/RW network of India

network. A profiler is an all-weather, unattended, vertically pointing clear-air Doppler radar. It comprises of a ground system for measuring the atmospheric wind parameters. Wind profiler system is capable of continuously measuring vertical profiles of wind speed and wind direction. IMD is planning to install systems, which

will operate at a fixed frequency in 420-435 MHz (tropospheric type with height coverage of around 10 kms) and 1200 to 1375 MHz band (boundary layer type with height coverage up to around 3 kms). The system includes all items necessary to measure, process, output, archive and display the atmospheric wind data. The

Fig. 4.8. A schematic representation of a Wind Profiler

data received from profilers can be used objectively by the assimilation of profiler observations into routine NWP model runs. At present there are two wind profilers operating from Pune and Gadanki. A typical wind profiler is shown in Fig.4.8

4.10. Microseism Observations

The seismological observatories are equipped with micro seismographs to record microseisms due to disturbed weather at sea. The seismographs at the coastal and island stations could be utilised during storm period. Microseism

observations could be differentiated as monsoon type, storm type etc. As far as operational use is concerned, it is restricted to detection of the presence of cyclonic storm. Large Microseism amplitudes are recorded, when the cyclonic storm is within 320 km from the coast. The forecasters seldom use microseism observations due to rapid strides made in Satellite and Radar meteorology.

4.11. Quality Control of Observations

In the forecasting offices, after the

reception of data from the field stations, discrepancies could be detected during the plotting of chart. The concerned observatory is asked to check and repeat the observation. The automatic message switching system installed at the regional telecommunication hub and at most of the regional meteorological centres has also a validation menu. Validation is done to check the format, header and text. Format validation checks the sequence number of message, whether “=” sign comes at end of the message etc. Header validation checks whether proper header is given for the message. Origin of the observation is also validated. A particular observation is expected only from its regional correction centre and if it comes from another centre, validation of the same is required.

Then the message is validated for text. Whether each group contains five digit numbers is checked and whether mandatory groups are included in the message. Then each group is validated. For example, if I_R were indicated as 2, system would check whether rainfall group is included. The system itself contains the extreme value limit for different weather elements for each station. Checking is done for each element. In some cases, provision for autocorrection is there. While running the Numerical weather prediction models, all the synoptic and upper air observations are used. These observations are once again checked before interpolation for generating the grid point values.

4.12. Radar Observations

Ten cyclone detection radars (10 cm –S band) are at present in operation in the country along the east and west coasts. The S-band radars at Chennai, Kolkata, Machilipatnam and Visakhapatnam have been replaced by Doppler Weather Radars (DWR). In addition a special DWR has been installed at Sriharikota (A.P). Along the west coast the installation of DWR at Mumbai has been completed.

4.12.1. Tracking by S-band Radars and Doppler Radars

The S-band radars operate at 10 cm wave length and give a good coverage for tracking the cyclones over the sea. Although the maximum range for cyclone detection radar is 500 km, the effective range is limited to 400 km mainly due to earth's curvature at long ranges. When a disturbance is approaching the coastal radar station directly, with the normal speed of about 10 – 15 km per hour, this range provides roughly a 24 hour tracking time between the first detection of the eye and the final landfall. A further period of a few hours may also be gained if well developed spiral band ahead of the centre of the cyclone appears first on the radar scope enabling determination of the centre with the help of spiral overlay technique.

Doppler Weather Radars provide vital information on radial velocity and spectral width, in addition to reflectivity which is also available from conventional (analog

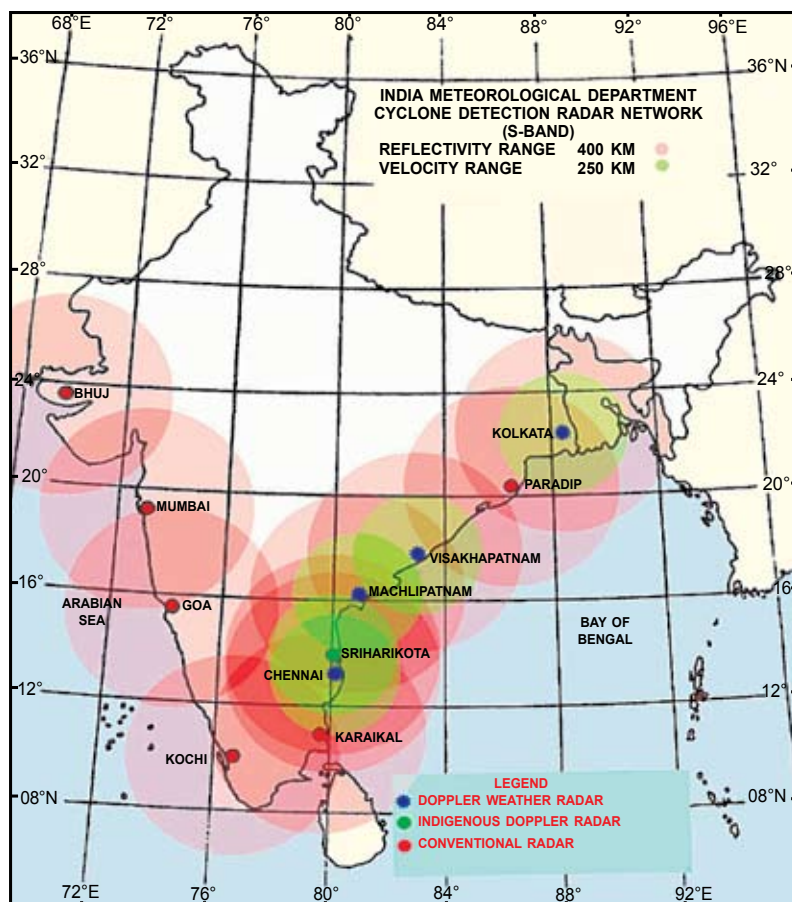

Fig. 4.9. S-band Cyclone Detection Radar Network

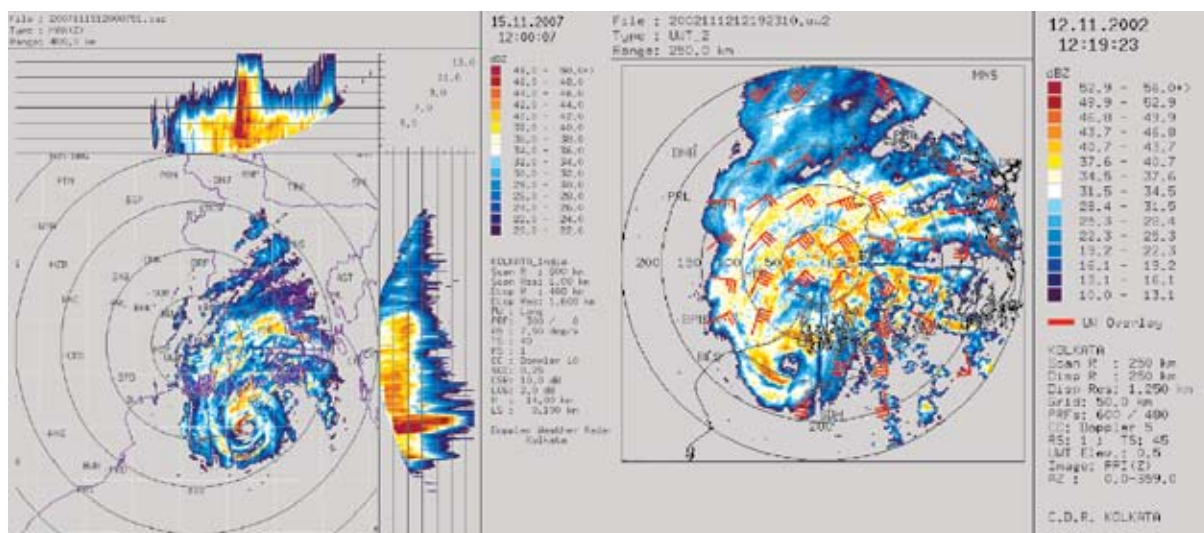

Fig. 4.10. Typical DWR products (Max Z and UWT) used for cyclone monitoring

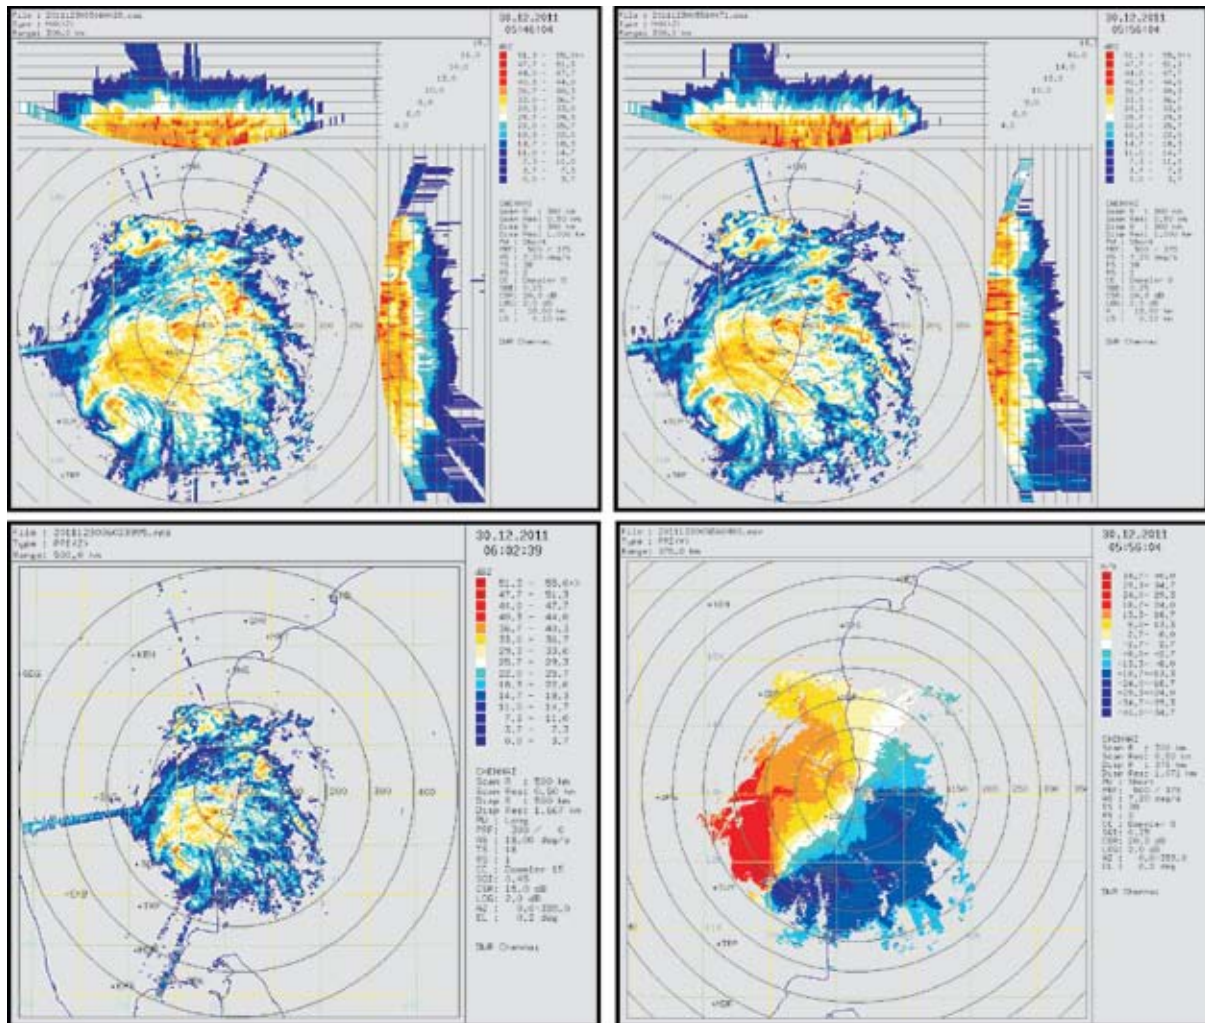

Fig. 4.11. Realtime PPZ, MAXZ & PPV images of cyclone THANE

type) of radars. However, the radial velocity information is restricted to 250 km only. Also the surface rainfall intensity estimation is possible and is restricted to a maximum of 150 km range due to the Earth curvature. Typical products are shown in Fig.4.10 and 4.11. Reflectivity estimates obtained from these radars are more accurate in comparison to those from conventional radars as the Doppler Weather Radars have capability for correcting the

values for clutters, partial beam filling, beam blockage and bright band. The Doppler Weather Radars generate various derived products in addition to primary PPI and RHI displays. Surface Rainfall Intensity (second level product derived from reflectivity) and other hydrological products like Precipitation Accumulation (PAC), Vertical Integrated Liquid (VIL) are very important for issuing warnings for heavy rain, flash flood and hail. The

algorithms for generation of these products employ some adaptable parameters which depend on drop size distribution (DSD) present in the precipitation. The DSD is different for different seasons, geographical location and type of precipitation. There are following three base data products, which are generated directly by the Doppler Weather Radar.

- Reflectivity (Z)
- Radial Velocity (V)
- Spectrum Width (W)

These base data products are displayed in website in the following format.

(a) Basic image products

- MAX(Z) Product
- Plan Position Indicator(Z)
- Plan Position Indicator, PPI(Z)-Close Range
- Volume Velocity Processing(2)
- Plan Position Indicator(V)
- Surface Rainfall Intensity
- Precipitation Accumulation (PAC) 24 hrs at 0300 UTC
- PCAPPI-1km
- Wind-1km

(b) RADAR animation

- MAX(Z) Product
- Plan Position Indicator(Z)

- Plan Position Indicator(V)
- Surface Rainfall Intensity
- Pseudo Constant Altitude PPI (PCAPPI)

(c) RADAR mosaic products

- Still image
- Animation 3 Hrs.

(d) Radar products in GIS

- Pseudo constant altitude PPI (PCAPPI)-1km
- Plan Position Indicator(Z)
- MaX(Z) Product
- Plan Position Indicator(Z)
- Volume Velocity Processing
- Wind-1km

Primary products

The products not available in website, but generated by the DWR include the following:

(a) Standard Met. Products:

- CAPPI -Constant Altitude PPI
- VCUT -Vertical Cut
- ETOP -Echo Top
- EBAS -Echo Base

(b) Extended Met. Products

- VAD -Velocity Azimuth Display
- UWT -Uniform Wind Technique

(c) Hydrological Products

- VIL -Vertical Integrated Liquid

(d) Shear Products

- RDS -Radial Shear
- AZS -Azimuthal Shear
- ELS -Elevation Shear
- RAS -Radial Azimuthal Shear
- RES -Radial Elevation Shear
- 3DS -3 D Shear
- HZS -Horizontal Shear
- VCS -Vertical Shear
- LTB -Layer Turbulence

(e) Warning & Forecasting Products

- HHW -Hail Warning
- TRK -Storm Tracking

4.12.2. Radars in Neighbouring Countries

Available information about cyclone warning radars in the neighbouring countries is given in Table 4.2 as a matter of interest. Occasionally, radar reports may be received from these radar centres. Also the radar products available from their concerned National Meteorological Services may be referred.

4.12.3. X-Band Radars**X-band radars along Coastal Belt**

The details of X-Band 3- cm radars that are functioning along the coast line of India are given in Table 4.3. X-Band EEC radars are Computer controlled state of art radars which provide product through software and pictures of cloud are presented in different colours according to the intensity

Table 4.2. Cyclone Warning Radars in the neighbouring countries

S. No.	Station Coast		Wave length	Remarks
1.	Kyaukpyu	Myanmar	10 cm	Operational since 1979

Table 4.3. X-Band 3- cm radars along the coast line of India

S.No.	Station name		Coast Remarks
1.	Kolkata	West Bengal	EEC X-Band ,Weather Radar
2.	Bhubaneswar	Odisha	EEC X-Band ,Wind Finding Radar
3.	Visakhapatnam	Andhra Pradesh	EEC X-Band, Wind Finding Radar
4.	Chennai	Tamil Nadu	EEC X-Band ,Weather Radar
5.	Thiruvananthapuram	Kerala	BEL X-Band, Wind Finding cum, Weather Radar
6.	Mangalore	Karnataka	EEC X- Band, Wind Finding Radar
7.	Panaji	Goa	EEC X-Band ,Wind Finding Radar
8.	Mumbai	Maharashtra	BEL X-Band ,Weather Radar
9.	Karaikal	Tamil Nadu	BEL X-Band ,Weather Radar
10.	Machilipatnam	Andhra Pradesh	BEL X-Band, Weather Radar

of the cloud. X-band EEC radars generate algorithm based derived products similar to reflectivity based products of Doppler weather Radar. EEC Wind finding radars have capability of being used as storm detection radars also.

The coastal X-band radars at Mangalore and Thiruvananthapuram may be used in storm situations affecting Karnataka and Kerala coasts; those at Mumbai, Goa, Chennai, Visakhapatnam and Kolkata will also be useful as a standby if the cyclone detection radars at these places become temporarily unserviceable. In case of unserviceability of the cyclone detection radar at Paradip, X-band radar at Bhubaneswar can serve as a standby.

4.12.4.Operation of Radar and Availability of Radar Observations

In undisturbed weather:

The cyclone detection radar will be operated as a routine at 0600 UTC every day for checking the overall performance of the radar. This will be the daily routine during undisturbed weather. There is no need to operate the radar beyond its routine operation when any system is more than 800 km. away from the radar station. The Doppler Weather Radar will be in continuous operation in all seasons.

When disturbances are developing:

Whenever a depression or cyclonic storm

lies between 400 and 800 km from the station and this information is conveyed to the radar station by ACWC/CWC or when precipitation echoes suggestive of development of a storm are observed on the radar-scope, the radar will be operated once every 3 hours (at full hours UTC).

Deep depressions and depressions

Hourly observations are adequate in the case of deep depressions and three hourly in the case of depressions within the range of the radar.

When storm is within the radar range

The radar is operated every hour or more frequently depending on the requirements concerned when the storm is within the radar range. The radar station will revert to routine only when the above conditions have ceased to be valid.

When eye is located

When the **eye** is located between 200 and 400 km. from the station, the radar is operated hourly, but more frequent observations (half hourly, or every 10 minutes) are made as required by the situation.

Continuous operation

The radar will be operated continuously, if necessary, when the cyclone center is at a distance of 200 km. or less from the radar station over the sea and until such time as the disturbance continues as a cyclone over land even after crossing coast.

The above paragraph refers to emergency measures and will apply only in the case of cyclonic storms. "Frequency of radar reports (RAREPs) is hourly and close co-ordination between officers of the Radar station and the associated Cyclone Warning Centre(s) is maintained for getting more frequent observations, if found necessary".

4.12.5. Radar Bulletin

Three hourly/hourly bulletins are prepared by Radar Centres and transmitted to concerned ACWCs/CWCs and CWD for use in Cyclone Warning. An example of such a bulletin in standard format is given in Table 4.4. The Radar stations can provide the location of cyclone to All India Radio (AIR) Stations when cyclone is tracked with confidence.

4.13. Satellite Cloud Imagery Data and Derived Products Useful in Cyclone Warning

4.13.1. Cloud Imagery Data

At present IMD is receiving and processing meteorological data from two Indian satellites namely Kalpana-1 and INSAT-3A. Kalpana-1 was launched on 12th September, 2002 and is located at 74° E. INSAT-3A was launched on 10 April, 2003 and is located at 93.5° E. Kalpana-1 and INSAT-3A both have three channel Very High Resolution Radiometer (VHRR) for imaging the Earth in Visible (0.55-0.75 μ m),

Infra-Red (10.5-12.5 μ m) and Water vapour (5.7-7.1 μ m) channels having resolution of 2X2 km. in visible and 8X8 km. in Water vapour (WV) and Infra red (IR) channels. In addition, the INSAT-3A has a three channel Charge Coupled Device (CCD) payload for imaging the earth in Visible (0.62-0.69 μ m), Near IR (0.77-0.86 μ m) and Short Wave IR (1.55-1.77 μ m) bands of Spectrum. The Resolution of CCD payload in all the three channels is 1kmx 1 km. At present about 48 nos. of satellite images are taken daily from Kalpana-1

which is the main operational satellite and 9 images are taken from INSAT-3A. Imaging from CCD is done 5 times during daytime only. All received data from the satellite are processed and archived in National Satellite Data Centre (NSDC), New Delhi.

Indian Meteorological Data Processing System (IMDPS) is processing meteorological data from INSAT VHRR and CCD data and supports all operational activities of the Satellite Meteorology Division on round the clock basis. Cloud

Table 4.4. Example of Radar based Cyclone Bulletin

Radar based Cyclone Bulletin	
Date : 30 th Dec._2011	Time: 06:00 UTC
Name of reporting Radar	Doppler Weather Radar, Chennai
Geo-coordinates of Radar	13.0728 N; 80.2883 E
Name of Cyclone	THANE
Main features visible at this time indicating:	
Centre	Eye not visible. Convergence of spiral bands indicates Vortex centre near 11.73 N 78.97 E (Azimuth 223.8 deg. Range 205.5 km). Confidence poor.
Intensity	Max reflectivity seen around the system centre is about 32 dBZ 23 dBZ echoes reach up to 9 km.
Velocity	Maximum radial velocity observed in the eye-wall region is around 28 mps on NW and -28 mps on SE sectors at about 206 km range /3.2 km height.
Other features, if any	System is moving WSWward at the rate of 19 kmph, during the past three hours
Remarks	40 th Bulletin on Thane. 201112300555_Real-time_PPZ , 300556_MAXZ, 300602_PPZ and 300556_PPV images attached. Hourly radar based bulletin is being discontinued as the system has weakened beyond reasonable estimation of features.

Imagery Data are processed and transmitted to forecasting offices of the IMD as well as to the other users in India and foreign countries.

To supplement these observations, cloud imagery data from METEOSAT-5 satellite, which is also located to observe Indian region, from 63 deg E long, are also being received in VIS (0.4-1.1mm), IR (10.5-12.5mm) and Water Vapour channels(5.7-7.1mm). Since all these satellites are geostationary satellites, cloud imagery data from these satellites are frequently ingested. It is 3 hourly in case of INSAT and half hourly in case of Kalpana-1 and ranges from half to one and half-hourly in case of METEOSAT-5 satellite. In addition to above mentioned geostationary satellites, cloud imagery data from the NOAA and METOP satellite are being received at HRPT stations at New Delhi, Chennai and at Guwahati whenever these satellites pass over Indian region. NOAA satellites pass over near local noon and near mid night at pre-assigned hours and normally imagery data in five/four channels are being received twice from each satellite during day/night pass. Apart from these six channel imagery data from NOAA AVHRR payload, TOVS data are also received from NOAA satellite for deriving temperature and moisture profiles. The cloud imagery radiance data from Kalpana geostationary satellite are used for making cloud Imageries and for deriving various Satellite Derived Products i.e., OLR, CMV, QPE &

SST. Cloud imageries are very useful for locating the tropical Cyclone position, its intensity by Dvorak Technique and speed and direction of movement and track of cyclone from sequence of imageries and the amount of convection associated with the tropical cyclone. The derived products help further in knowing these aspects of a cyclone. Both cloud imagery and the Derived Products help in diagnosing and forecasting the tropical cyclone intensity and position.

4.13.2.Derived Products Used for Diagnosing a Tropical Cyclone

Several products, which can be used in meteorology in general, are derived from satellite cloud imagery radiance data. Following products are available with Kalpana cloud imagery data. Apart from generating half hourly cloud imagery, IMDPS produces derived products from the processed data as follows:

- Cloud Motion Vectors (CMV) are derived with 2.5° resolution using three consecutive half hourly images from the operational Kalpana-I Satellite. CMVs are generated at 00, 03, 06, 09, 12, 15, 18 and 21 UTC using IR imagery daily.
- Water Vapour Winds (WVWs) are derived with 12.5° resolution using three consecutive half hourly images from the operational Kalpana-I Satellite. WVWs are generated at 00, 03, 06, 09, 12,

Fig. 4.12. Wind data available through satellites

15, 18 and 21 UTC using water vapour imageries data.

These CMV's/WVWs are being transmitted on MDD for utilization by other forecasting stations. These wind data are useful in monitoring tropical cyclones location and intensity (Fig.4.12).

- Sea Surface Temperatures (SST) are computed at $1^{\circ} \times 1^{\circ}$ grid intervals from all Kalpana-I data on half hourly /daily /weekly/monthly basis. These SST are available on nearly cloud free regions. Unfortunately, where there is a tropical cyclone, SSTs are not available due to heavy cloudiness. Yet SST before the TC formation are helpful in deciding the probable region for generation of a TC.
- Outgoing Longwave Radiation (OLR) are computed at $0.25^{\circ} \times 0.25^{\circ}$ grid

intervals from all Kalpana-I data on half hourly /daily /weekly/monthly basis. OLR patterns are being derived from IR cloud imagery Radiance data and the same are also transmitted for use at other forecasting centres. These OLR patterns although useful for forecasting TC intensity, also find application in numerical models and for rough estimation of direction of movement and intensity of convection present. OLRs are averaged daily, weekly and monthly.

- Quantitative Precipitation Estimation (QPE) is generated at $1^{\circ} \times 1^{\circ}$ Grid from Kalpana-1 imagery on half hourly/ daily/weekly/monthly basis. These are also transmitted on MDD. The QPE are useable in finding the precipitation potential of a TC.

- At present Dvorak technique is widely used but manually applied. Recently efforts have been made for automation of this technique. Automated Dvorak technique is running in experimental mode at Satellite Meteorology Division of IMD.

4.13.3. Tropical Cyclone Bulletins Based on Satellite Cloud Imagery Data and Derived Products

During normal weather 3-hourly Bulletins called Satellite Bulletins based on satellite cloud imagery data and derived products are made at Satellite Meteorology Division of IMD, New Delhi. These 3-hourly bulletins are transmitted through MDD for utilization by forecasting offices. But when there is a tropical cyclone over the Bay of Bengal or the Arabian Sea, these Satellite Bulletins are prepared each hour and transmitted

through MDD. In these bulletins, the centre and intensity of cyclone as estimated by Dvorak Technique, its past motion and amount of convection associated with tropical cyclones and other characteristic features are described.

Based on different satellite cloud imagery data and their derived products, the US Weather Bureau, Washington, issues daily bulletins called “Satellite Tropical Disturbance Summary”(STDS) for the different oceanic areas, describing the major cloud system and disturbed weather area. The information contained in the STDS includes location and intensity of the tropical systems, if any, in the area, their past movement, associated cloud bands etc. The intensity and related details are given in Dvorak’s T-code form. The summary for the Indian Ocean covers

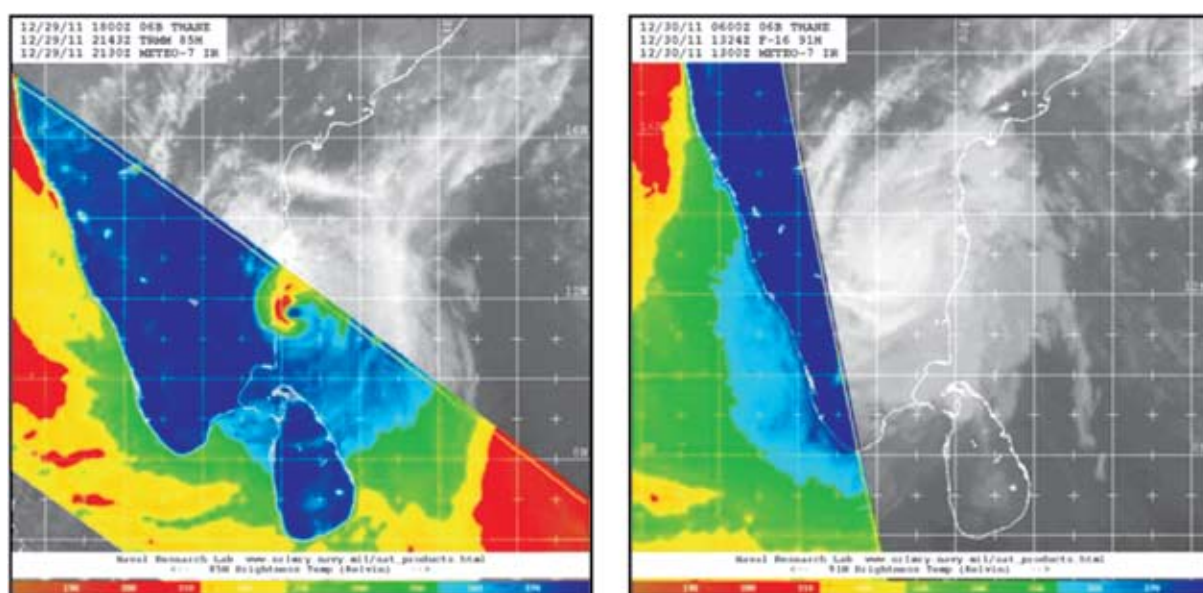

Fig. 4.13. Microwave imagerys of TC THANE

Arabaian Sea and Bay of Bengal also. These bulletins are received at New Delhi on the GTS and retransmitted to the ACWCs/CWCs, Weather Central Pune and other Forecasting Offices in India. As these are received only after a lapse of some hours after the picture time, they may not be useful for immediate operational purposes. However, they are utilized for comparing our assessment of the centre and intensity of the system with that of the U.S. Weather Bureau.

Satellite information about disturbances

over the Indian seas is also available in the storm warning bulletins issued from U.S. Fleet Weather Central (Joint Typhoon Warning Centre-JTWC). This is based on the pictures received through the satellites of the Defence Met. Satellite Programme (DMSP) of U.S.A. These bulletins are also received at New Delhi on the GTS and distributed to the concerned offices. Recently the microwave imageries are also used to monitor the TCs especially their genesis, location and intensity. A typical microwave imagery of a TC is shown in Fig. 4.13

Monitoring and Prediction Technique

5.1. Monitoring and Prediction of Cyclogenesis

Following steps are followed for monitoring and prediction of cyclogenesis (formation of depression) over the north Indian Ocean.

5.1.1. Road Map

Step I

- Location of deep convection areas on geostationary satellite imagery (on Synergie)
- Presence of a pre-existing disturbance in the lower atmosphere : analysis of pre-existing lows in the ITCZ (their location, organization, intensity)
- Animated visible and IR geostationary imagery on Synergie : estimation of the areas of organizing deep convection, their evolution during the last 24 hours; first estimation of associated LLCCs (low level circulation centers); analysis of exposed LLCCs (when out of deep convection).
- Micro-Wave imagery over suspected convective areas (Monterey website, or Synergie Cyclone), to see the low or mid-level improving cyclonic

organization, under Cirrus clouds. (http://www.nrlmry.navy.mil/tc_pages/tc_home.html)

Step II

- Ocean surface winds derived from satellite:
- OSCAT : <http://manati.orbit.nesdis.noaa.gov/oscat/> Ocean Surface Winds derived from the SeaWinds Scatterometer aboard the Ocean Sat II satellite
- ASCAT : <http://manati.orbit.nesdis.noaa.gov/ascat/> Ocean Surface Vector Winds derived from the Advanced Scatterometer (ASCAT - 50km) aboard the EUMETSAT METOP satellite
- WINDSAT : <http://manati.orbit.nesdis.noaa.gov/windsat/> Ocean Surface Winds derived from WindSat/Coriolis Measurements

Step III

SST exceeding 26°C and a deep thermocline (50 m)

- Analysis of SST in models available in Synergie
- <http://www.aoml.noaa.gov/phod/cyclone/data/ni.html>

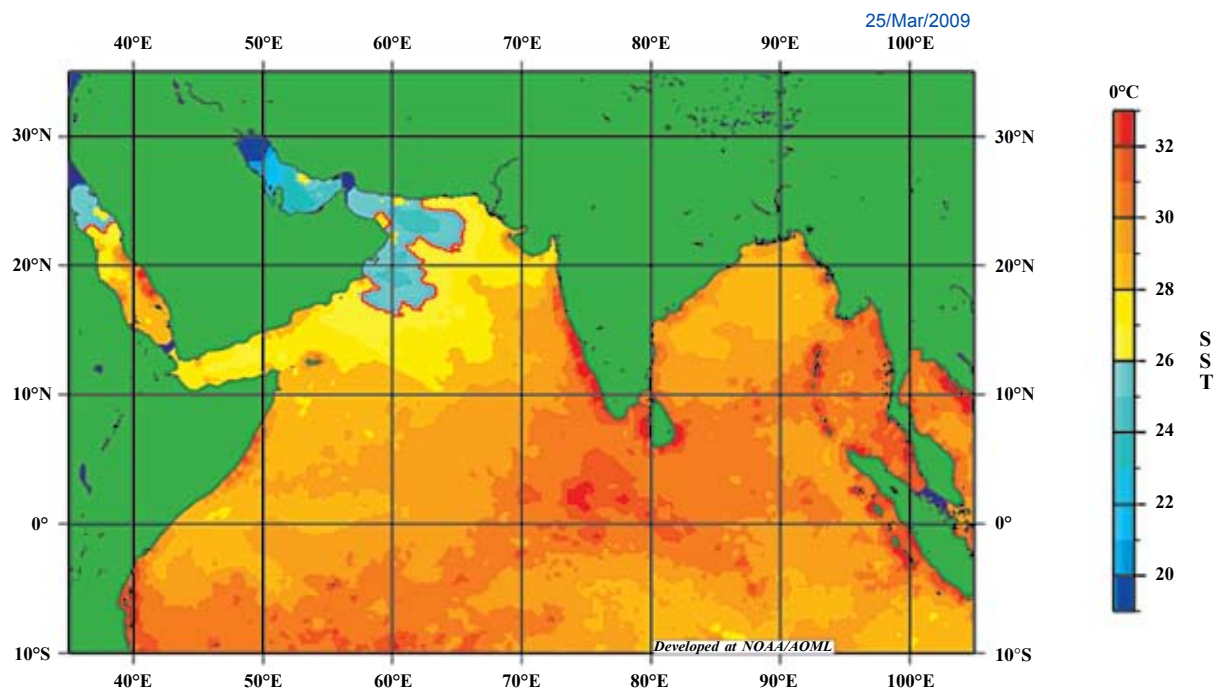

Fig. 5.1. SST as on 25th March, 2009

- IMD (Satellite)
- Depth of the 26°C isotherm. SST field provided on a daily basis from TMI measurements (Tropical Rainfall Measuring Mission's Microwave Imager).
- SST from TMI (Fig.5.1 as an example)
- Estimation derived from Sea Height Anomaly on altimeter satellite observation.
- Ocean Thermal Energy
- Area of deep convection on satellite imagery
- Favorable synoptic scale conditions for development of deep convection (Madden Julian Oscillation (MJO)/ Outgoing Longwave Radiation (OLR)) : http://www.bom.gov.au/bmrc/clfor/cfstaff/matw/maproom/OLR_modes/
- Maps of the MJO real-time filtered OLR anomalies, each averaged for a period of 7 days. The first map is for the most recent 7 days of observed data (Fig.5.2). 3 subsequent maps are the forecasts of the MJO OLR anomalies. Blue shading is an indication of enhanced convection and rainfall. Orange shading is an indication of suppressed conditions Tropical lows

Step IV

- Conditional instability through a deep atmospheric layer

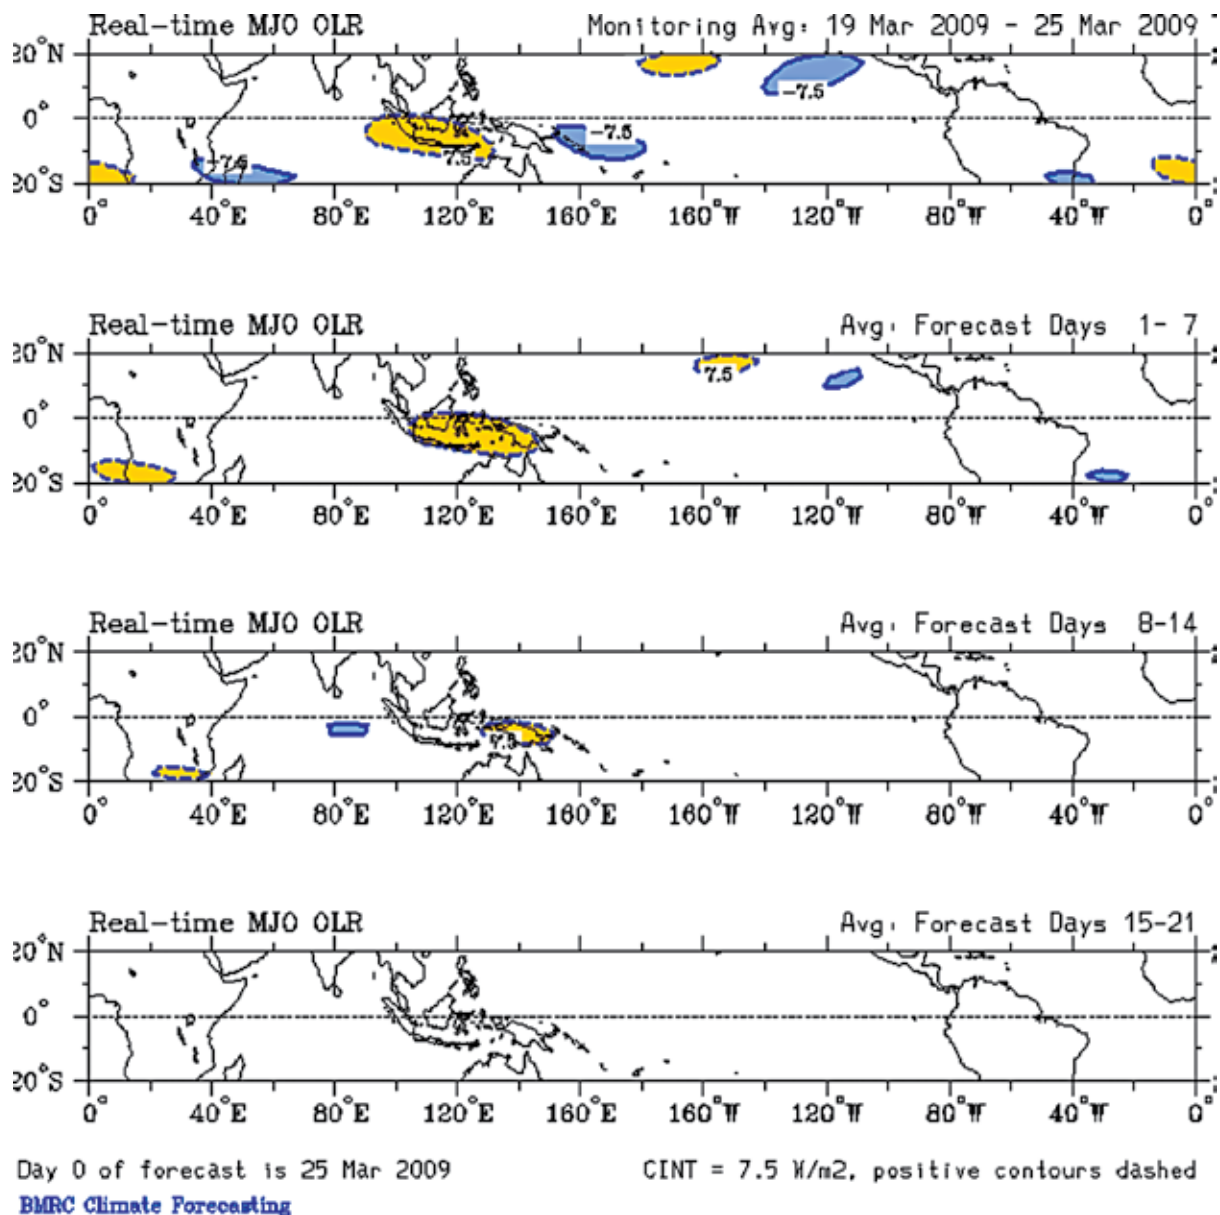

Fig. 5.2. Real-time MJO-OLR forecast

mainly develop during enhanced or neutral convection phase.

- Forecast of (Poor or No) risk of development up to 7 days possible when dry phase is forecast.

Step V

- Large values of relative humidity in the lower and middle troposphere.

Step VI

- ❖ Significant value of planetary vorticity

(Coriolis force) ~5 degrees distance from Equator.

Tropical storm has been observed at 2.5° distance from equator sometimes also

❖ Weak vertical shear of the horizontal winds

- Upper level winds at 200/300 hPa (<http://cimss.ssec.wisc.edu/tropic2/>)

- Wind Shear based on satellite observation is defined as follows.

Wind Shear = (150-300) hpa layer mean minus (700-925) hpa layer mean

Wind shear is classified as follows:

5-10 kt : weak (favorable for development)

10-20 kt: moderate (unfavorable for weak system, or neutral for mature cyclone)

>20 kt : strong (unfavorable)

❖ Good upper level outflow

- Models analysis

❖ Good low level inflow

- Models analysis
- Low level winds data (Ocean Sat-II)

5.1.2. Tools to Use for Tropical Activity Daily Watch

❖ VIS and IR geostationary animation over the last 24 hours

- Superimposed with EIR in Dvorak colors
- Observations data

❖ Synergie Macro for each available numerical models

- SLP (Sea Level Pressure)
- Absolute Vorticity at 850 hPa (only negative values) : measures the rotation of air over itself. A minimum of Ta850 shows deep convection organizing with circulation.
- Low level winds (Favorable low level surges, or inflows, with trade wind or monsoon wind)
- Upper level winds (200 hPa) : upper level outflows, high or ridges favorable for good divergence, vertical wind sheared areas etc.

❖ Internet data :

- Scatterometry winds
- Micro-wave imagery for developing lows
- CIMSS maps (vertical wind shear, upper level divergence etc.)
- MJO/OLR dry or enhanced convection phases.

5.1.3. Methodology for Tropical Activity Daily Watch

(i) First step is rapid analysis of the tropical convective activity

- Is it poor, moderate or strong?
- What is its evolution during the last 24 hours?
- The deep convection has intensified or not (in geographical extension, in intensity, coldness of Cb's top and in cyclonic organization)?
- Comparison must be done with the days before at the same hours, to avoid to be influenced by the diurnal effect over ocean. Deep convection naturally intensifies (deepness and extension) during the night, between 15 UTC and 02 UTC (maximum of deep convective activity at the end of the night, near 23 UTC-01UTC).

(ii) Whether existence of deep convection clusters since more than 24 hours?

(iii) Is there one (or several) associated low level circulation center(s) (LLCCs)? Estimation of their location, motion and intensity (MSLP and associated max mean winds) by :

- Satellite imagery (classical and Micro-wave), scatterometry data, surface observations.
- Estimation of their potential for intensification :

- Numerical models forecasts
- Analysis of the environment : SST, OLR, Wind shear, low level inflows, upper level outflows, Potential vorticity, Potential temperature

(iv) Estimation of the risk for development of a depression

- No risk, risk poor, moderate, or high?
- At least for the next 24 hours
- Beyond, if possible :
- If all the NWP models develop a significant low in the same area and at the same range and show the formation of depression in 36-48 hrs : "for the next 24 hours, the risk for development of a Depression is poor, but it becomes moderate near.... for the next 36 to 48 hours"
- If all the NWP models do not develop anything, in a dry phase of MJO : "there is no risk for development of a Depression during the next 3 days"

5.2. Monitoring of Cyclonic Disturbances (Depression and Above)

The cyclone monitoring and forecasting aims at providing information to the public and disaster management agencies on the following aspects:

- a. The current location and intensity of the cyclone
- b. Associated sustained maximum wind, estimated central pressure, pressure drop at the centre, shape and size of cyclone.
- c. Past movement, speed and direction
- d. Forecasting the intensity and track, wind distribution, radii of quadrant wind for different thresholds like 28, 34, 50 and 64 knots
- e. Time and location of landfall
- f. Coastal areas likely to be affected by gale force wind and their time of occurrence
- g. Estimated height of tidal waves/ Storm surge/ the part of the coast likely to be affected by tidal waves /storm surge and the time of occurrence
- h. Area to be affected by heavy/ very heavy/ extremely rainfall and the time of occurrence.
- i. State of sea and wave height

The monitoring and prediction of location and intensity of the system is mainly based on (a) Synoptic, (b) satellite and (c) radar observations. When system is far out at sea, satellite observation is given more weightage. When it comes within radar range, radar is given higher weightage followed by satellite and synoptic observations. When the system is close to coast, the synoptic observation gets maximum weightage followed by Radar and satellite.

Fig. 5.3. Position and Intensity of a tropical cyclone by Dvorak Technique

The average confidence level of locating the centre of the system over the NIO is about 50 km. It should, however, be borne in mind that in the case of relatively weaker system, the available radar and satellite pictures are much less decisive and it is more difficult to locate and estimate the intensity of the system.

There can be small differences in the location of the centres by the different methods, such as radar, satellite, synoptic observations etc. However, if the system is intense and well defined eye is reported by radar, then the radar center should be taken in view of its greater accuracy. Even here, several workers have reported systematic differences upto about 50 km between the eye seen in the radar and that reported by aircraft reconnaissance flight.

5.2.1. Synoptic Analysis

The analysis of synoptic observations is performed four times daily at 00, 06, 12, and 18 UTC. During cyclonic disturbances (depression and above intensity), synoptic charts are prepared and analysed every three hour to monitor the tropical cyclones over the north Indian Ocean. The centre of the cyclonic disturbance is synoptically defined as the point of lowest pressure in the pressure field and the centroid of the cyclonic wind field. In the 10 meter wind field, a perpendicular is drawn from the direction of the wind. The meeting point of these perpendiculars determines the

centre of the disturbance. In case there are two or more meeting points, the centroid determines the centre of disturbance.

When the system comes closer to the coastline, the system location and intensity are determined based on hourly observations from CDR and DWR stations as well as coastal observatories. The AWS stations along coast are also very useful as they provide hourly observations on real time basis. The WVV and CMV in addition to the conventional wind vectors observed by Radio Wind (RW) instruments are very useful for monitoring and prediction of cyclonic disturbance, especially over the Sea region.

A new weather analysis and forecasting system has been installed at IMD, New Delhi, which has the capability to plot and analyse different weather parameters, INSAT & radar imagery and NWP products using PC software known as SYNERGIE procured from Meteo France International (MFI). It has a tropical cyclone module, to deal with various aspects of cyclonic disturbance.

The direction and speed of the movement of a tropical cyclone are determined primarily from the three hourly displacement vectors of the centre of the system and by analyzing satellite imageries.

5.2.2. Satellite Analysis

Dvorak technique with its international algorithm has been the mainstay of

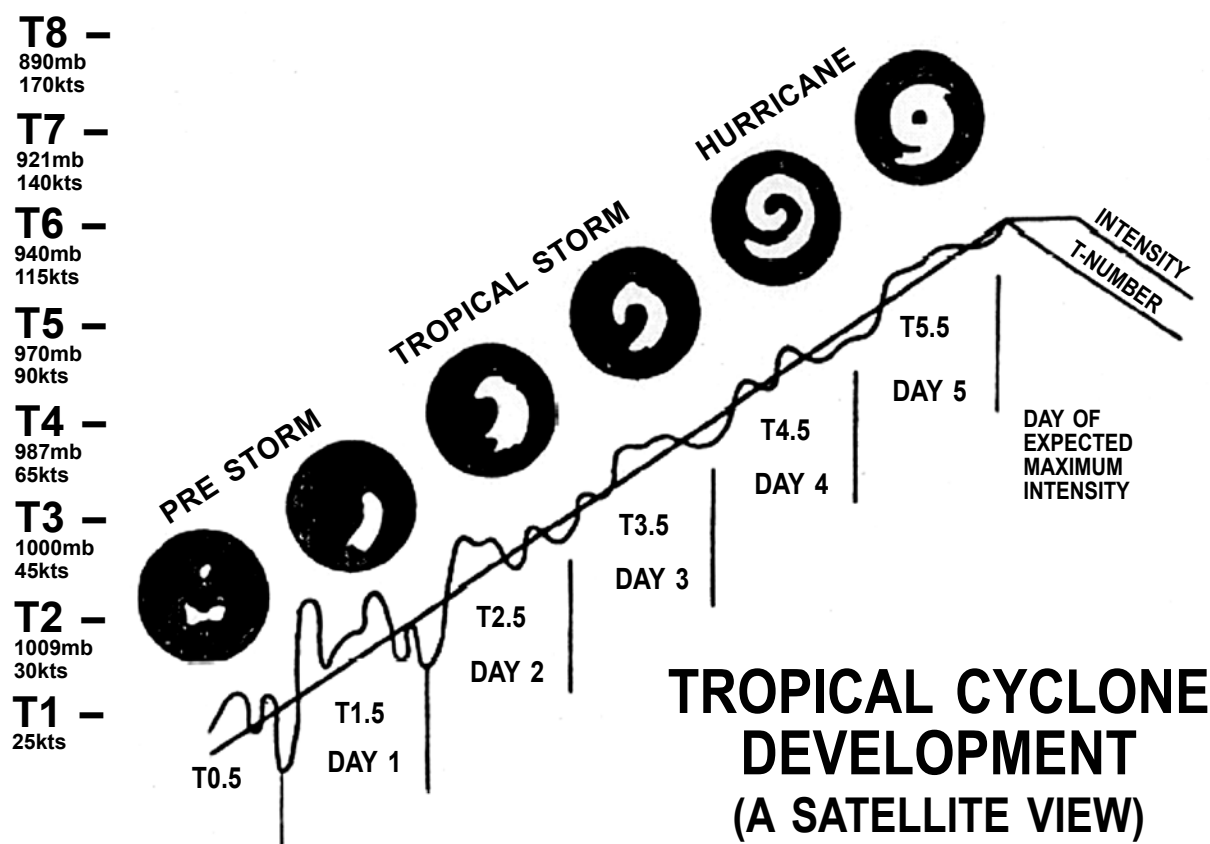

Fig. 5.4. Model of tropical cyclone development used in Intensity analysis

analysis, particularly of intensity of TCs. Cloud imageries from Geostationary Meteorological Satellites INSAT-3A and METSAT (KALPANA-1) are the main sources of information for the analysis of tropical cyclones over the data-sparse region of north Indian Ocean. Data from Ocean buoys also provide vital information. Ship observations are also used critically during the cyclonic disturbance period.

5.2.2.1. Position and Intensity of a Tropical Cyclone by Dvorak Technique

Dvorak Technique is basically a pattern recognition technique. The technique relies

on four distinct geographical properties that relate organized cloud pattern to cyclone intensity. Two are kinematic namely vorticity and vertical wind shear and the other two are thermodynamical viz. convection and core temperature. The strength and distribution of circular winds (by implication vorticity) in a cyclone organizes the cloud into the patterns that Dvorak relates to maximum sustained surface wind (MSW). External/environmental shear is a kinematic force that works to distort the vorticity and hence the cloud pattern. Dvorak found that degree of distortion was also related to maximum sustained wind.

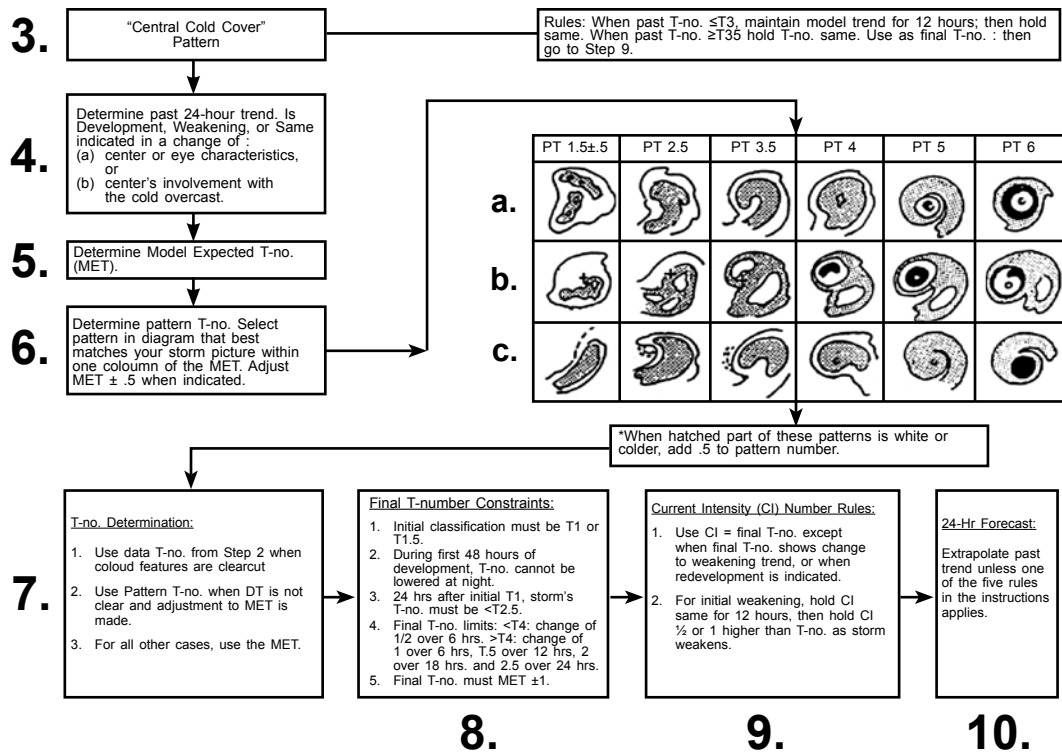

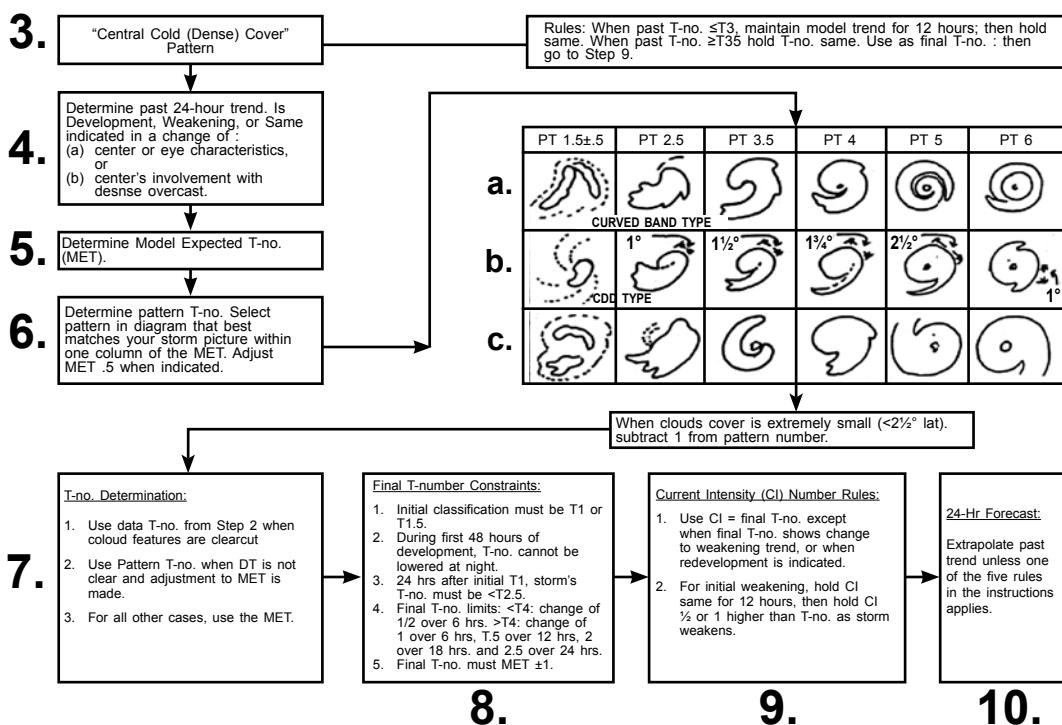

(a) EIR Analysis Diagram-2**(b) VIS Analysis Diagram-2**

Fig. 5.5(a). EIR analysis diagram for determining the Intensity. **(b).** Vis analysis diagram for determining the Intensity

Both visible and IR imageries are used is Dvorak pattern recognition technique. Detailed methodology for determining the intensity is shown in fig. 5.4 and 5.5 (a-b).

Dvorak Technique uses a scale from T1 to T8 in the interval of 0.5.

This classification of intensity is based on two parameters arrived at on an analysis of the cloud features as seen in the satellite pictures of the disturbance. These are 1) the central features which define the cloud system centre and its relation to dense overcast clouds (CF) and 2) the outer banding features (BF). The intensity of the tropical system is indicated by a code figure called T Number which is the sum of the central feature (CF) and banding features (BF).

In curved band pattern convection in the bands of outer core of the cyclone is used in pattern recognition by Dvorak Technique using satellite measured IR cloud temperature in the cyclone inner core. Dvorak Technique relates convective vigour to the intensity of the system.

In central dense overcast (CDO) pattern, size and temperature of the CDO determines the intensity. In shear pattern, the distance between the LLCC and the sharp boundary of the connective cloud determines the intensity of the system.

In case of cyclones with eyes, the technique determines the temperature of the eye and the surrounding eye wall clouds using

IR data and relates to the intensity with warmer/cooler eye/wall cloud temperatures respectively indicating greater intensity.

Another feature of the technique is the Current Intensity number (C.I.) which relates directly to the intensity (in term of wind speed) of the cyclone. The C.I. number may differ from the T number on some occasions to account for certain factors which are not directly related to cloud features. The empirical relationship between C.I. number and the maximum wind speeds (according to Dvorak) are given in Table 5.1. Col. 3 of the Table 5.1 gives the pressure depths (peripheral pressure minus central pressure in hPa) as applicable for Indian Sea area using the relation $V_{max} = 14.2 \times \text{SQRT} (P_n - P_o)$.

The centre of the low level cyclonic circulation as evident from the low cloud lines is considered as the centre of the system. As during night the visible imagery is not available, the low cloud lines cannot be detected. As a result, the location of the centre during night time cannot be determined correctly. It is more so when it is a low intensity system like depression/ cyclonic storm. When the system intensifies into a severe cyclone with appearance of eye feature, the location of the centre becomes most accurate and it is the centre of the eye. The eye can be detected in both visible and IR imageries. Further in case of curved band pattern or CDO pattern centre can be more accurately determined compared to shear pattern. The centre

Table 5.1. Dvorak's classification of cyclonic disturbances

<i>C.I. Number</i>	<i>Max. Wind Speed (MSW) (knots)</i>	<i>Pressure drop (hPa)</i>
1.0	25	3.1
1.5	25	3.1
2.0	30	4.5
2.5	35	6.1
3.0	45	10.0
3.5	55	15.0
4.0	65	20.9
4.5	77	29.4
5.0	90	40.2
5.5	102	51.6
6.0	115	65.6
6.5	127	80.0
7.0	140	97.2
7.5	155	119.1
8.0	170	143.3

determined by logarithmic spirals fitted to the curved band pattern determines the centre of the system. The centre of the CDO pattern similarly is taken as the centre of cyclone. The centre of low cloud lines is the only solution to determine the centre of cyclone in case of shear pattern and hence, the error in determining the location of the centre at night is maximum in case of shear pattern.

To overcome the above problems, the microwave imageries can be utilized. Microwave imageries at night can detect

the cloud features and hence the centre of cyclone as the microwave radiation can penetrate through the clouds associated with the cyclone. Example of determination of centre and intensity of the cyclone using logarithmic spirals in satellite imagery is shown in Fig.5.3

5.2.3. Radar Techniques for Fixing Centre and Intensity of Cyclone

The techniques for fixing the centre is given briefly below to serve as a background

material to the forecaster in interpreting the radar pictures, or sketches or RAREP messages received at the forecasting centers. The eye or the centre of the cyclone can be derived from a continuous and logical sequence of observations. The geometric centre of the echo-free area will be reported as the *eye location*. If the wall cloud is not completely closed, it is still usually possible to derive an eye location with a high degree of confidence by sketching the smallest circle or oval that can be superimposed on the inner edge of the existing portion of the wall cloud. When the wall cloud is not developed fully but a centre of circulation is identifiable, then this feature should be observed and reported similar to the eye. When the eye or centre is indistinct or outside the range or the radar beam overshoots the inner eyewall when it does not extend very high, spiral band overlays are used to estimate the location of the centre. Use of logarithmic spirals has been described in detail in the Appendix II of Chapter 5 of instructions for Cyclone Detection Radar stations in I. Met. D. *Weather Radar Observations Manual* – 1976. At times, instead of fully *closed eye*, only an arc of an eye wall may be seen which is reported as *open eye*.

Information on various characteristics of the eye wall cloud and changes thereof, is often useful to the meteorologist in assessing the intensity of the cyclone.

Thus the decrease in size of a closed eye with time is usually an indication of intensification. Changes in the definition of the eye wall, improvement in its symmetry, the angle of arc visible, the radar echo intensity and the heights of echo tops in the eye wall are usually associated with changes in intensity of the storm.

Hence when an eye is seen on radar, the radar meteorologist should try to give as much information as possible on the above parameters. When the wall cloud is within a range of 200 km from the radar, the echo intensity and the echo top heights at various points should also be objectively evaluated using the isoecho/attenuator facilities and the RHI scope and applying necessary corrections. The information may be included in the appropriate code in the radar reports. Wherever necessary, additional information in plain language can be given. The polar diagrams may also be annotated to give this information.

This information should however be used with caution by the forecaster. There can be appreciable measurement errors in echo heights and intensities. The changes in anyone parameter may be only poorly correlated with storm intensity. There can also be considerable time-lag between the observed changes in eye characteristics and the changes in the winds and pressure associated with the system.

5.3. Characteristics of Cyclonic Disturbance

5.3.1. Maximum Wind

Maximum wind is determined basically from Dvorak's technique. However the following technique is followed for better accuracy:

1. Wind reported by ships and buoys.
2. Wind observed by scatterometry i.e. OCEANSAT & ASCAT.
3. Radar
4. CMV/ AMV reduced to 10 meter wind

5.3.2. Estimated Central Pressure (ECP)

Estimated Central Pressure is derived basically by Dvorak's technique as given in Table 5.1. Also the pressure reported by ship, buoy, coastal/island observation is taken into consideration.

5.3.3. Pressure Drop ΔP

Pressure drop at the centre is given by difference of central pressure and pressure of outermost closed isobar.

ΔP = Pressure of Outer most closed isobar (P_o) - Central pressure (P_c)

Relation between maximum wind and pressure drop is given by:

$$V_{\max} = 14.2 \times \text{Sqrt}(\Delta P)$$

From the value of V_{\max} , ΔP is calculated. Once ΔP and P_o are known, P_c can be

calculated. The Table 5.1 can be used to calculate V_{\max} and ΔP .

5.3.4. Radius of Maximum Wind (RMW)

There is no direct observation of Radius of Maximum Wind (RMW). It is the distance of location of maximum wind from the centre of the cyclone. It is estimated from maximum wind and place of occurrence as discussed above. In addition RMW can be calculated from satellite and radar. In radar the radius of maximum reflectivity is considered as RMW. In satellite the radius of maximum reflectivity in visible imagery and the radius of lowest cloud temperature in IR imagery is considered as RMW. In the absence of reliable observations climatology may be referred to estimate RMW.

5.3.5. Heavy Rain

Realised heavy rain can be analysed from (1) Actual observations. (2) Quantitative Precipitation Estimate (QPE) from satellite (3) Surface Rainfall Intensity (SRI) from Radar. (4) Tropical Rainfall Measurement Mission (TRMM). The distribution and intensity of rainfall is described as given in Table 5.2 and 5.3 respectively.

5.3.6. State of Sea

State of sea is described in bulletin in qualitative terms as given in Table 5.4. The sea condition is described based on the prevailing wind condition. Though it is qualitative, it corresponds to the height of

Table 5.2. Distribution of rainfall

Distribution	No. Of places	Description
Isolated	One or two places	<25% of area gets rainfall
Scattered	A few places	(26 –50)% of area gets rainfall
Fairly Widespread	Many places	(51 – 75)% of area gets rainfall
Wide Spread	Most places	(76 – 100)% of area gets rainfall

Table 5.3. Intensity of rainfall

Descriptive term used	Rainfall amount in mm
No rain	0.0
Very light rain	0.1- 2.4
Light rain	2.5 – 7.5
Moderate rain	7.6 – 35.5
Rather heavy	35.6 – 64.4
Heavy rain	64.5 – 124.4
Very heavy rain	124.5 – 244.4
Extremely heavy rain	244.5 or more
Exceptionally heavy rain	When the amount is a value near about highest recorded rainfall at or near the station for the month or season. However, this term will be used only when the actual rainfall amount exceeds 12 cm.

the wave as mentioned in the table. Further the sea condition may be analysed based on NWP models. The following websites should be followed for this purpose.

1. INCOIS: <http://www.incois.gov.in>
2. NCMRWF: <http://www.ncmrwf.gov.in/>
3. ECMWF: <http://www.ecmwf.int>

5.4. Prediction of Characteristics of Cyclonic Disturbances

Following elements are predicted.

- (i) Track
- (ii) Intensity (Maximum wind)
- (iii) Radius of maximum wind

Table 5.4. Sea Condition

Descriptive Term	Height in metres	Wind Speed in Knots (kmph)	Beaufort Scale
Calm (glassy)	0	0	0
Calm (rippled)	0 - 0.1	1 - 3 (2 - 6)	1
Smooth (waveless)	0.1 - 0.5	4 - 10 (7 - 19)	2 - 3
Slight	0.5 - 1.25	11 - 16 (20 - 30)	4
Moderate	1.25 - 2.5	17 - 21 (31 - 39)	5
Rough	2.5 - 4.0	22 - 27 (41 - 50)	6
Very rough	4.0 - 6.0	28 - 33 (52 - 61)	7
High	6.0 - 9.0	34 - 40 (63 - 74)	8
Very high	9.0 - 14.0	41 - 63 (76 - 117)	9 - 11
Phenomenal	Over 14	64 or above (119 or above)	12

- (iv) Radii of 28, 34, 50 and 64 knots wind in four quadrants
- (v) Heavy rainfall (Time of occurrence, area of occurrence, intensity)
- (iv) Squally/Gale wind at the time of landfall (Time of occurrence, area of occurrence, intensity)
- (vii) Storm surge (Time of occurrence, area of occurrence, height and area to be inundated)

5.4.1. TC Analysis Tools and Techniques

Various kinds of analytical procedure are described in Cyclone Manual (IMD, 2003). A systematic check list is prepared for identification of location and intensity of TC and also for the prediction of track and intensity. The procedure necessarily deals

with determination of location and intensity along with other characteristics of the TC like associated sustained maximum wind, estimated central pressure and pressure drop at the centre, shape and size, radius of outermost closed isobar, point and time of landfall, if any or area of dissipation etc. with the available observations in the storm region.

To ensure the availability of the data and forecast products from various national and international sources at Cyclone Warning Division, IMD, New Delhi, an institutional mechanism has been developed in consultation with all the stake holders.

The TC analysis, prediction and decision-making process is made by blending scientifically based conceptual models, dynamical & statistical models,

meteorological datasets, technology and expertise. Data from conventional observational network, AWS, buoy & ship observations, cyclone detection radars and satellites are used for this purpose. A weather analysis and forecasting system in a digital environment is used to plot and analyse different weather parameters, satellite, Radar and numerical weather prediction (NWP) model products. The manual synoptic weather forecasting has been replaced by hybrid systems in which synoptic method could be overlaid on NWP models supported by modern graphical and GIS applications to produce high quality analyses and forecast products. The automation of the process has increased the efficiency of system, visibility of IMD and utility of warning products. The TC Module installed in this forecasting system has the following facilities.

- Analysis of all synoptic, satellite and NWP model products for genesis,

intensity and track monitoring and prediction

- Preparation of past and forecast tracks upto 120 hrs
- Depiction of uncertainty in track forecast
- Structure forecasting (Forecast of wind in different sectors of cyclone)

A few examples on the products of TC Module are shown in Figure 5.6. However all the data are not still available in TC Module through synergie system. For better monitoring and prediction, additional help is taken of ftp and websites to collect and analyse:

- Radar data and products from IMD's radar network and neighbouring countries
- Satellite imageries and products from IMD and international centres

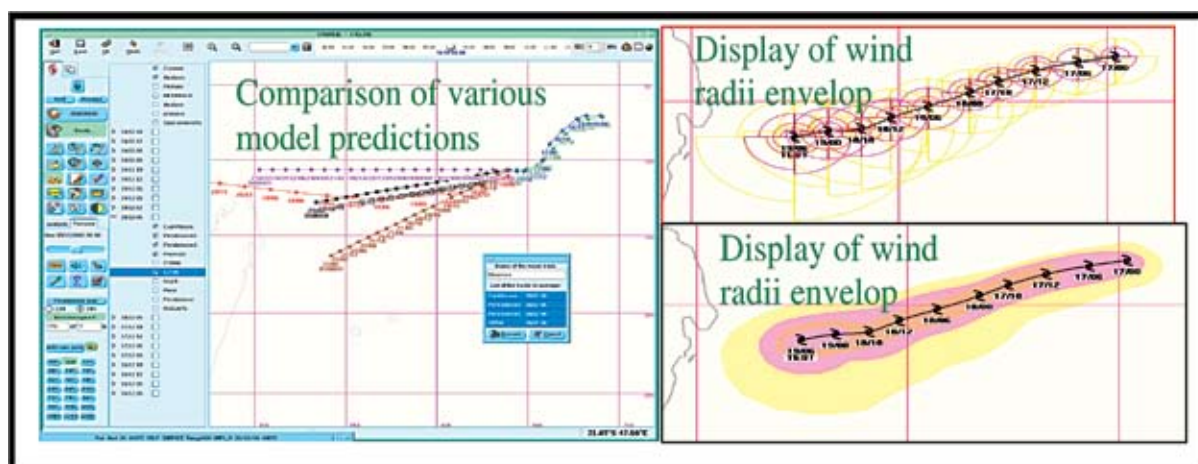

Fig. 5.6. Utility of modernised cyclone analysis and forecasting system

- Data, analysis and forecast products from various national and international centres

5.4.2. Cyclone Track Forecasting

Currently following methods are used by IMD for TC track forecasting.

i) Statistical Techniques

- Analogue
- Persistence
- Climatology
- Climatology and Persistence (CLIPER)
- Chaos theory and Generic Algorithm method) developed by Indian Space Research Organisation (ISRO)

ii) Synoptic Techniques – Empirical techniques

iii) Satellite Techniques- Empirical techniques

iv) Radar Techniques- Empirical techniques

v) NWP Models

- Individual models (Global and regional)
- IMDGFS (382, 574), ARP (Meteo-France), ECMWF, JMA, UKMO, NCEP, WRF (IMD, IITD, IAF), HWRF (IMD), Quasi-Lagrangian model (QLM)

- Multimodel ensemble (MME)-(IMD) and MME based on TC Module (TCM)

- Ensemble prediction system (EPS) (Strike probability, Location specific probability) based on GFS, UKMO, ECMWF models etc.

- TIGGE EPS products

Following NWP products from deterministic models are considered useful for cyclone warning apart from track and intensity forecast.

- ❖ Analysed and forecast grid point fields of basic flow variables at different pressure levels:
- ❖ Sea level pressure
- ❖ Geopotential
- ❖ Wind
- ❖ Temperature
- ❖ Humidity
- ❖ Forecast rainfall
- ❖ Derived fields :
 - Vorticity
 - Divergence
 - Vertical motion
 - Integrated moisture flux divergence
 - Precipitable water
 - Vertical wind shear
 - Equivalent potential temperature and its lapse rate.

- Convective Available Potential Energy (CAPE) and Convective Inhibition Energy (CINE)

Apart from the above models, the model products from INCOIS/NCMRWF and storm surge models of IIT, Delhi are considered for wave forecasting and storm surge prediction. Examples of track prediction by individual models in case of TC, Rashmi and EPS product in case of TC, Jal are shown in Fig.5.7(a) and Fig.5.7(b) respectively.

Unlike National Hurricane Centre (NHC), USA, IMD does not use the interpolated track forecasts from the late models. All

the NWP models as mentioned above except QLM are late models as the model output is available to forecasters as late as six to twelve hrs. The QLM is a near real time model and the statistical models like CLIPER and ISRO model are real time models. Similarly all the NWP models as mentioned above do not use synthetic vortex and vortex relocation. While QLM, NCEP use synthetic vortex, global model like ECMWF does not use these processes.

In the synoptic method, prevailing environmental conditions like wind shear, low to upper level wind and other characteristics

Ensemble track forecast of cyclone JAL

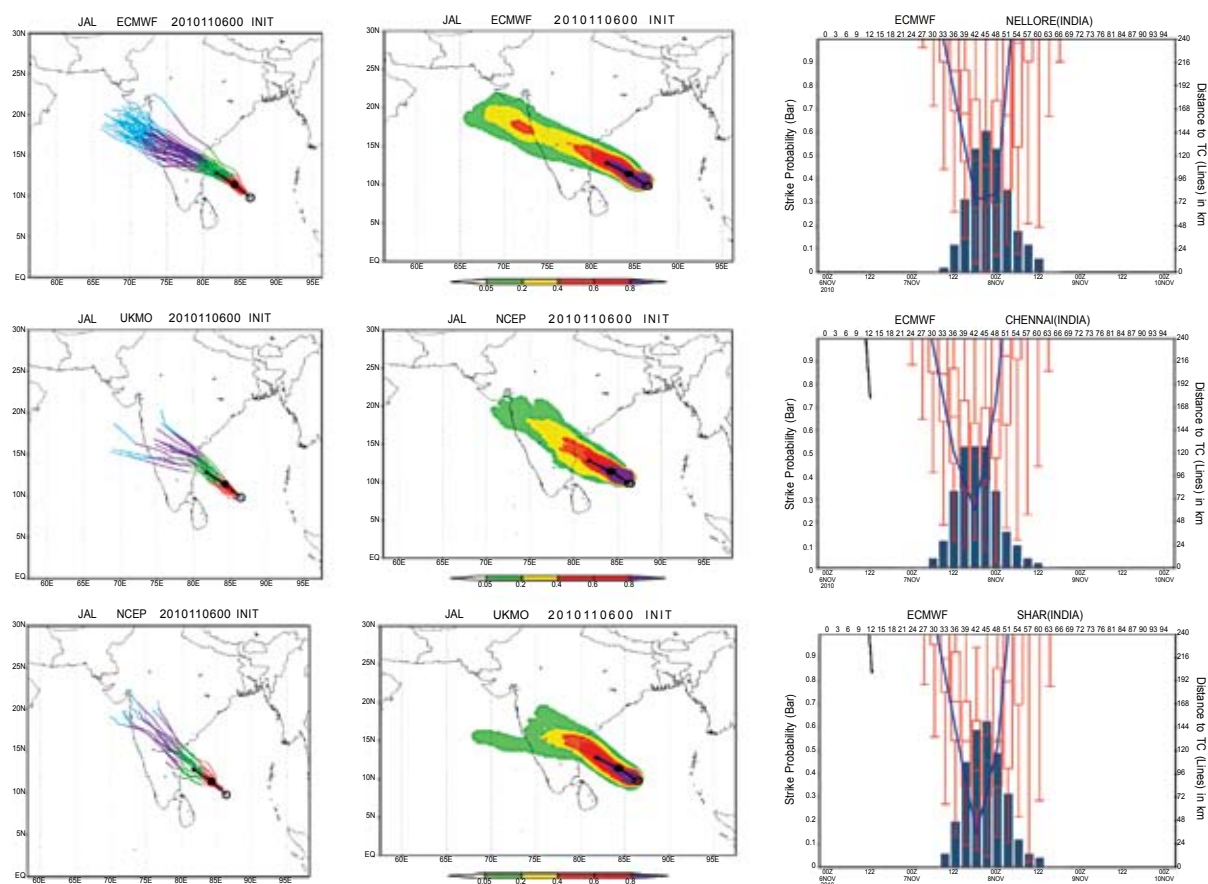

Fig. 5.7 (b). Track prediction of TC, JAL by EPS

as mentioned in cyclone manual and check list (IMD, 2003) are considered. All these fields in the NWP model analyses and forecasts are also considered. The development of characteristic features in satellite and radar observations is also taken into consideration for predicting the track. While, the synoptic, statistical and satellite/radar guidances help in short range track forecast (upto 12 hrs), the NWP guidance is mainly used for 24-72 hr forecasts. Hence, the RSMC forecast tracks result from a manually analyzed

forecasting process, which relies on output from several NWP models (RSMC, 2010) as discussed above. Consensus forecasts that gather all or part of the numerical forecast tracks and uses synoptic and statistical guidance are utilised to issue official forecast.

IMD introduced the objective TC track forecast valid for next 24 hrs over the NIO in 2003. It further extended the validity period upto 72 hrs in 2009. The track forecast has been issued by RSMC, New

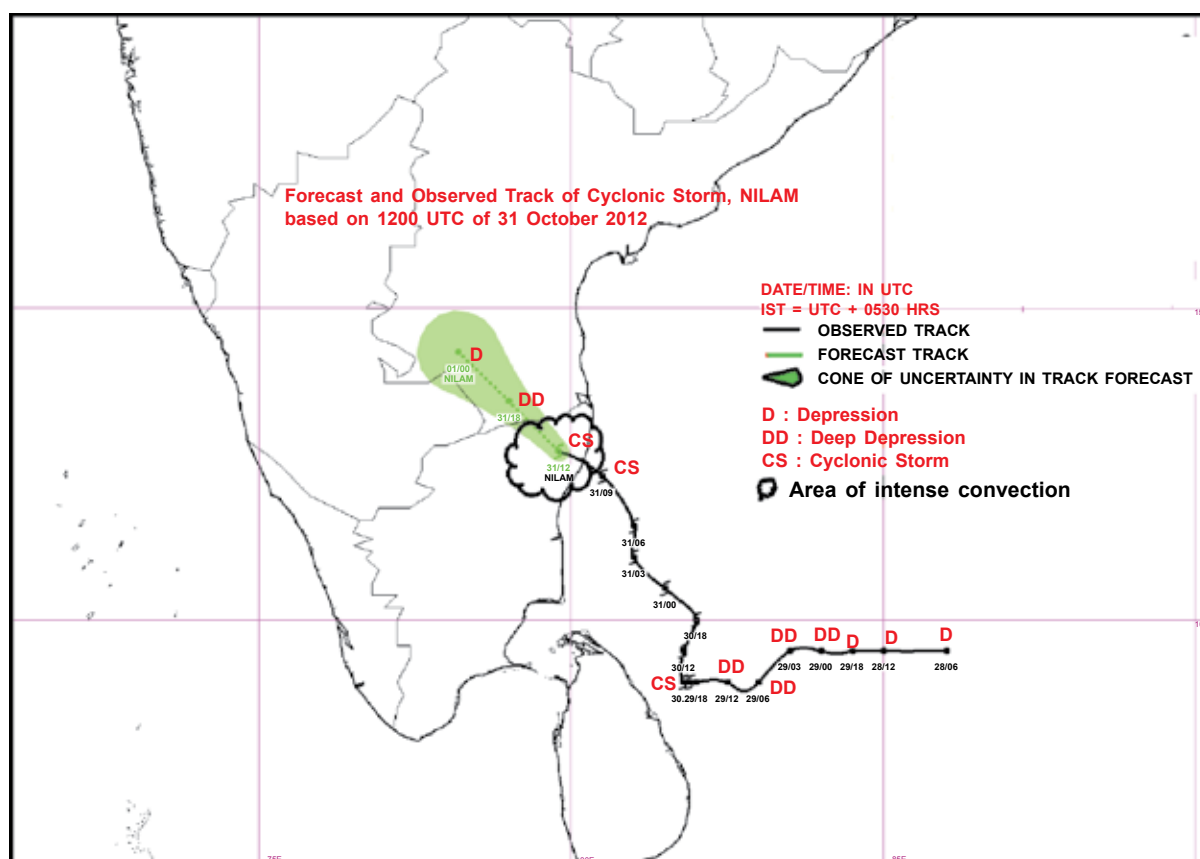

Fig.5.8. Observed and forecast track of Cyclonic Storm NILAM with cone of uncertainty

Delhi from deep depression stage onwards since 2009 for 12, 24, 36, 48, 60 and 72 hr forecast periods. The TC forecast is issued 6 times a day at the interval of three hours, i.e. based on 00, 03, 06, 09, 12, 15, 18 and 21 UTC observations. The forecasts are issued about three hours after the above mentioned observation time. An example of the product during cyclone Nilam is shown in Figure 5.8. It may be mentioned that the RSMC, Tokyo introduced 24 hr objective forecast in 1982, 48 hr forecast in 1988, 72 hr forecast in 1997 and 96 & 120 hr forecast in 2009 for northwest Pacific Ocean. Similarly, National

Hurricane Centre and RSMC, Miami, USA introduced 24 hr objective forecast in 1954, 48 hr forecast in 1961, 72 hr forecast in 1972 and 96 & 120 hr forecast in 2001 for Atlantic Ocean. Prior to 2003, the TC forecasts issued by IMD for the NIO were subjective and textual in form without mentioning expected location of the TC in 12 and 24 hr forecast period.

5.4.3. Cone of Uncertainty in Track Forecast

The “Cone of Uncertainty (COU)”-also known colloquially as the “cone of death,” “cone of probability,” and “cone of error”-

represents the forecast track of the centre of a TC and the likely error in the forecast track based on predictive skill of past years. Most World meteorological Organisation (WMO) designated RSMCs for TCs including Miami, Florida; Tokyo, Japan; and Hawaii, USA and TC Warning Centers (TCWCs) currently display COU around their official track forecasts, using a climatological method based on their area of responsibility. For each forecast lead time, an uncertainty circle is built whose radius is taken as a fixed quantile (e.g., 67% for Miami, 70% for Tokyo) of the distribution of direct position error (DPE) computed over several previous seasons. The Joint Typhoon Warning Centre (JTWC) in Hawaii produces COU for TCs over Pacific Ocean and Indian Ocean, whose radii are the sum of the climatological average DPE and the predicted 34-knot wind radius.

The COU in the forecast has been introduced with effect from the cyclone, 'WARD' during December, 2009. It is helpful to the decision makers as it indicates the standard forecast errors in the forecast for different periods like 12, 24, 36, 48, 60 and 72 hrs. The radii of circles used to construct the COU are 75, 150, 200, 250, 300 and 350 km respectively for 12, 24, 36, 48, 60 and 72 hrs forecasts based on past average errors of official forecasts for 12 and 24 hrs forecast and of QLM for 36-72 hr forecasts. It is found that the observed track lies within the

forecast COU in about 60% of the cases. It is in agreement with those over other Ocean basins. The entire track of the TC remains within the COU roughly 60-70% of the time over the northern Atlantic Ocean and Pacific Oceans.

5.4.4. Intensity Forecasting

The intensity forecast has been issued by RSMC, New Delhi from deep depression stage onwards since 2009 for 12, 24, 36, 48, 60 and 72 hr forecast periods. It has been issued during CS stage onwards during 2003-2008 and for 12 and 24 hrs forecast periods only. The TC intensity forecast is issued 4 times a day at the interval of six hours, i.e. based on 00, 06, 12 and 18 UTC observations valid upto 24 hrs during 2003-2008 and upto 72 hrs since 2009 in every three hourly intervals. The forecasts are issued about three hours after the above mentioned observation time. Following methods are used by IMD for intensity forecasting of TCs over the NIO.

- i) Statistical Techniques
 - a. Analogue
 - b. Persistence
 - c. Climatology
- ii) Synoptic Technique – Empirical Techniques
- iii) Satellite Technique – Empirical technique
- iv) Radar Technique – Empirical

technique

v) NWP Models

- Individual models (Global and regional)
- IMDGFS (382, 574), ARP (Meteo-France), ECMWF, JMA, UKMO, NCEP
- WRF (IMD, IITD, IAF), HWRF (IMD)

vi) Dynamical Statistical Model (Statistical Cyclone Intensity Prediction-SCIP).

5.4.4.1. Statistical Dynamical Model for Cyclone Intensity Prediction

A statistical-dynamical model for cyclone intensity prediction (SCIP) has been implemented for real time forecasting of 12 hourly intensity upto 72 hours. The model parameters are derived based on model analysis fields of past cyclones. The parameters selected as predictors are: Initial storm intensity, Intensity changes during past 12 hours, Storm motion speed, Initial storm latitude position, Vertical wind shear averaged along the storm track, Vorticity at 850 hPa, Divergence at 200 hPa and Sea Surface Temperature (SST). For the real-time forecasting, model parameters are derived based on the forecast fields of ECMWF model. The method is found to be promising for the operational use.

There is no CLIPER model for intensity prediction unlike the Atlantic and Pacific basins. In the synoptic method, prevailing

environmental conditions like wind shear, sea surface temperature, Ocean thermal energy, low level inflow, upper level outflow etc as mentioned in the section 5.1.1 for genesis are considered for intensification also. All these fields in the NWP model analysis and forecasts are also considered. The development of characteristic features in satellite and radar observations is also taken into consideration for predicting the intensity. While, the synoptic, statistical and satellite/radar guidances help in short range intensity forecast (upto 12/24 hrs), the NWP guidance is mainly used for 24-72 hr forecasts. Hence, the RSMC, New Delhi official forecast intensity results from a manually analyzed forecasting process, which relies on output from several NWP models as mentioned above. Consensus forecasts that gather all or part of the numerical forecast intensities and uses synoptic and statistical guidance are utilised to issue official forecast.

5.4.5. Quadrant Wind Forecasting

The TC wind radii forecasts are generated in terms of the radii of 34kts, 50kts and 64kts (1kt = 0.52 ms⁻¹ or 1.85 kmph) winds in four geographical quadrants around the TC (thereafter referred to individually as R34, R50 and R64 for 34kts, 50kts and 64kts wind thresholds respectively or collectively as wind radii in units of nautical miles (1nm=1.85km)). These wind radii represent the maximum radial extent of winds reaching 34kts, 50kts and 64kts in

each quadrant. The initial estimation and forecast of the wind radii of TC is rather subjective and strongly dependent on the data availability, climatology and analysis methods. The subjectivity and reliance on climatology is amplified in NIO in the absence of aircraft observations. However, recently with the advent of easily accessible remote sensing derived surface and near surface winds (e.g. Ocean Sat., Special Sensor Microwave Imager (SSMI), low level atmospheric motion vectors and Advanced Microwave Sounder Unit (AMSU) retrieval methods) and advances in real time data analysis capabilities, IMD introduced TC wind radii monitoring and prediction product in Oct.,2010. The inputs for monitoring are obtained from following observations

- ❖ Ship
- ❖ Buoy
- ❖ OceanSat.
- ❖ Lower level Atmospheric Motion Vectors
- ❖ Cloud Motion Vectors
- ❖ Water vapour based wind vectors
- ❖ Special Sensor Microwave Imager (SSMI) data
- ❖ Advanced Microwave Sounder Unit (AMSU)
- ❖ Latest advances in real time data analysis capabilities
- ❖ DWR(when system is within the radar range
- ❖ Coastal wind observations

The initial wind radii estimates have become less subjective due to the tools and products mentioned above. While better initial estimates of R34, R50 and R64 are becoming available, forecasting these wind radii remains a difficult task. It is mainly because of the fact that we do not have any objective wind radii forecast methods and current NWP models fail to produce forecasts that are better than climatology.

The road map for monitoring and prediction of quadrant wind radii is given below.

- (a) Date and time of initial condition
- (b) Official location and Intensity (T/C.I. No., maximum wind and centre position)
- (c) Initial TC wind radii estimation
 - Wind radii based on Oceansat/ ASCAT/Windsat wind
 - SSMI based wind radii
 - Wind radii based on lower level atmospheric motion vectors
 - Wind radii by AMSU retrieval method
 - Wind radii based on global and regional NWP model analyses
 - Wind radii based on DWR wind retrieval
 - Value addition based on coastal, ship and buoy observations
 - Climatological consideration
- (d) Official forecast of TC intensity and track upto 72 hrs.

- (e) Persistence forecast based on initial wind radii and past 12 hrs trend.
- (f) Climatological forecast of TC wind radii.
- (g) NWP Model forecasts of 10 metre wind radii
 - Select the model most appropriate to initial condition
 - Compare the wind field distribution to the actual wind
 - Calculate the wind radii in four quadrants for the threshold of 34kts, 50kts and 64kts surface wind
 - Make corrections based on actual

wind, climatology, intensity of the system and radius of maximum wind

- (h) Official TC wind radii forecast in four quadrants for the threshold of 34kts, 50kts and 64kts based on S.N. (b-g)

A typical example of the quadrant wind radii product is shown in Fig.5.9.

5.4.6. Prediction of Heavy Rainfall

The following are the parameters for prediction of rainfall

- Time of commencement
- Duration

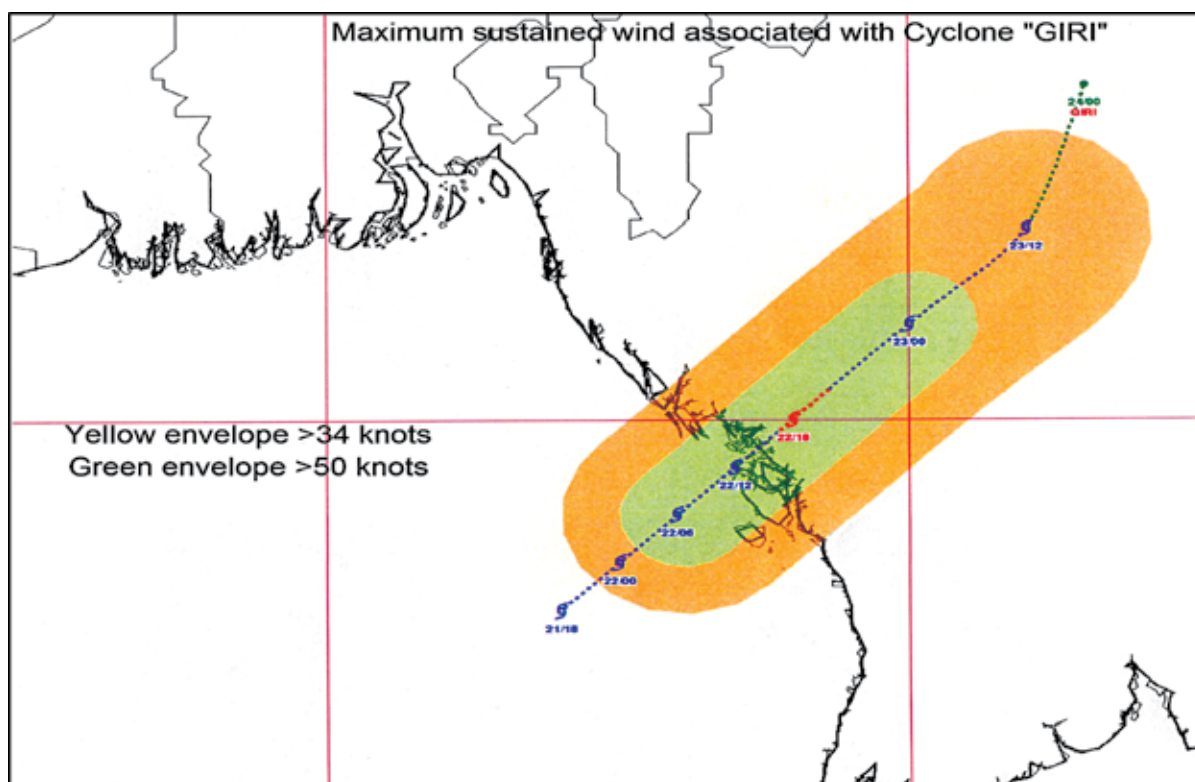

Fig. 5.9. A typical graphical presentation of quadrant wind forecast during cyclonic storm GIRI

- Area
- Intensity

The followings are the methods for prediction of heavy rainfall

- Synoptic method
- Climatology method
- Satellite method
- Radar technique
- NWP technique

Typical rainfall prediction by NWP model in association with cyclone Phyan is shown in Fig. 5.10. While NWP technique provides prediction for different lead period, Satellite and radar provides quantitative precipitation estimates during past 3/12/24 hrs. The intensity and spatial distribution of rainfall estimated by satellite and radar are extrapolated to issue forecast. In synoptic and climatology method, synoptic

climatology of rainfall, intensity and spatial distribution are used. In this method the forecast depends on the expertise of the forecaster. The final forecast is the consensus arrived from various methods as mentioned above.

5.4.7. Prediction of Gale Wind at Landfall

The followings are the parameters for prediction of gale wind

- Time of commencement
- Duration
- Area
- Intensity

The following methods are utilised for prediction of gale wind

- Synoptic method

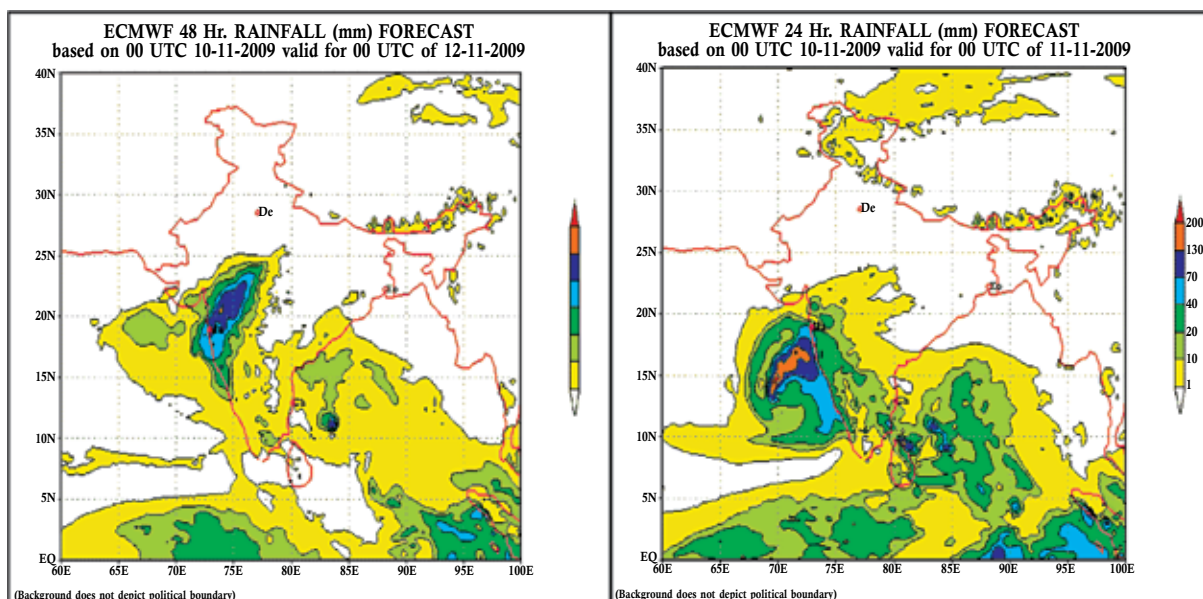

Fig. 5.10. Typical rainfall prediction by NWP model

- Climatological method
- Satellite method (T number, region of maximum reflectivity and mesoscale vortices)
- Radar technique (Uniform wind technique, PPV2 and Radial Velocity)
- NWP technique (10 meter wind forecast)
- Dynamical statistical model

In the satellite method region of maximum reflectivity and mesoscale vortices are assumed to be associated with higher wind. In radar technique, the direct wind observation are available though uniform IMD technique, PPV2 product and radii velocity measurements. The wind estimates from satellite and radar and other observations are extrapolated to forecast the wind. Maximum sustained wind are also available from other sources like Scatterometry wind (Oceansat, Wind sat, ASCAT), Buoy and Ship apart from that estimated by Dvorak technique.

Though the wind forecasts by the models are mostly underestimated, the initial condition of wind from the model can be corrected based on actual observations and accordingly model forecast wind can be derived. The forecast based on dynamical statistical model also can be utilised in the similar manner.

5.4.8. Storm Surge

The followings are the parameters for prediction of storm surge.

- Time of commencement
- Duration
- Area
- Intensity

The followings are the methods used for prediction of storm surge

- IMD Nomogram (Ghosh model)
- IIT Delhi Model
- Probable maximum storm surge

Nomogram and IIT Delhi model are used to calculate the storm surge. The probable maximum storm surge should be referred while issuing storm surge forecast for comparison.

5.4.8.1. Nomograms

Ghosh model nomograms are based on the numerical solution to the hydrodynamical equations governing motion of the Sea. The nomograms are prepared relating peak surge with various parameters such as pressure drop, radius of maximum wind, vector motion of the cyclone and offshore bathymetry.

5.4.8.2. IIT Delhi Storm Surge Model

The dynamical model of IIT Delhi is fully non-linear and is forced by wind stress and quadratic bottom friction following the method of numerical solution to the

vertically integrated mass continuity and momentum equations. The updated version of the model currently in operational use covers an analysis area lying between lat. 2.0° N and 22.25° N and long. 65.0° E & 100.0° E. The meteorological, hydrodynamical and bathymetry parameters are the inputs for this model.

The method uses a conditionally Table semi-implicit finite difference stair step scheme with staggered grid for numerical solution of the model equation. The bottom stress is computed from the depth-

integrated current using conventional quadratic equation. The bathymetry of the model is derived from Naval Hydrographic charts applying cubic spline technique. The storm surge models developed by IIT, Delhi (IITD) for different Panel member countries have been installed at RSMC, New Delhi. It is providing storm surge guidance to member countries in tropical cyclone advisory bulletin since April, 2009. An example of storm Surge Prediction by IITD model is shown in Fig. 5.11. The storm surge prediction is largely dependent on

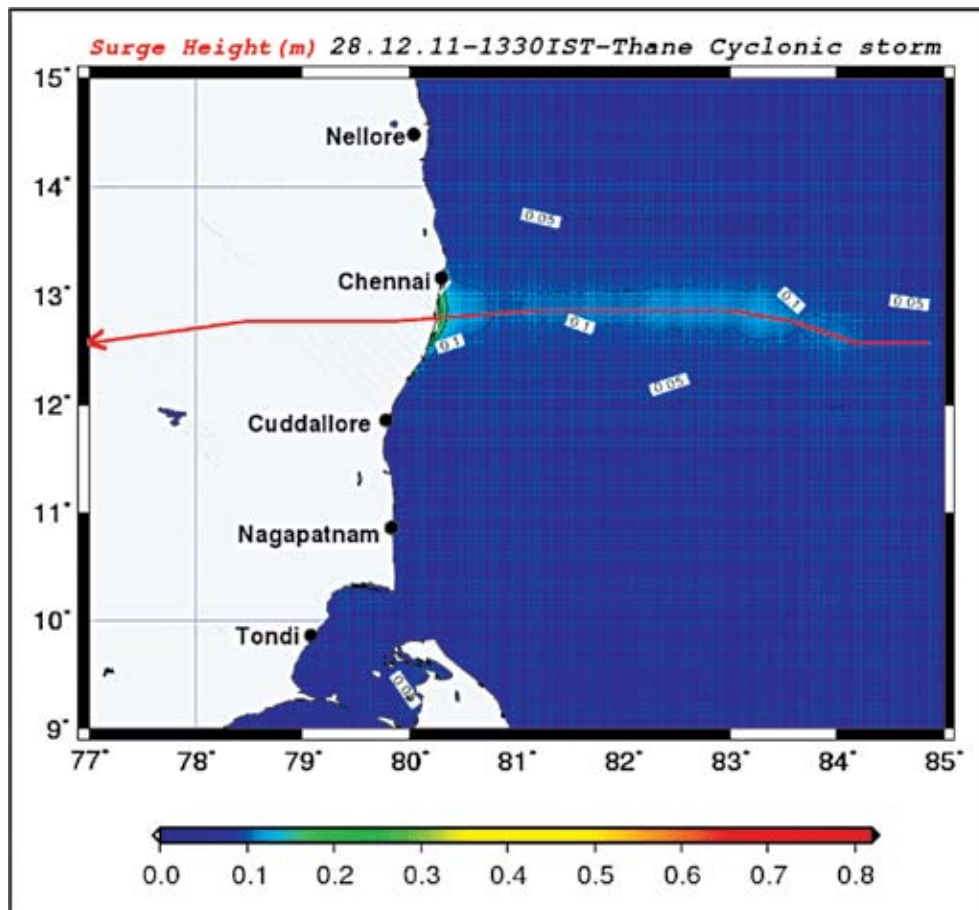

Fig. 5.11. Typical storm surge prediction by IITD model in case of VSCS 'THANE'

the predicted characteristics of the cyclones like, track, intensity and point of landfall.

5.5. Check List for Decision Making

The very process of the detection and forecasting of the cyclonic storm should be made logical, all technical features should be identified and given due place in reaching conclusions so that no snap decisions based on preconceived notions are taken. The conclusions should be arrived at step by step. It is essential therefore that a check list for decision making should be devised and the forecaster meticulously fills in all the technical details available and skillfully draws conclusions.

The check list should be prepared for all steps of cyclone monitoring and prediction as mentioned below.

- ❖ Genesis
- ❖ Monitoring of location shape, size, intensity and wind distribution
- ❖ Forecast location, intensity, movement, wind distribution and sea conditions.
- ❖ Landfall processes
 - Heavy rain
 - Gale wind
 - Storm surge

The detailed check list for this purpose is given below. For further details about the physical features, the Forecasting Manual/ Cyclone Manual can be referred to.

Bulletins and Warning

6.1 Introduction

The design of a TC warning system in IMD takes into consideration of the prevailing state of the meteorological science, the available technological means of communication, the built-up environment such as dwellings, socio-economic conditions, appropriateness of protective actions as well as the expectations of the society. To maximise relevance and effectiveness of the TC warning, strategies are formulated in respect of the design of the forecast, triggering mechanisms, coordination with disaster management agencies, warning products generation, presentation & dissemination. Scientific and technological advances in TC forecasting are translated into effectiveness of TC warning. The forecast and warning operations and decision-making process is made by blending scientifically based conceptual models, meteorological datasets, technology and expertise. Various bulletins issued by IMD are as follows.

1. Bulletins issued by RSMC, New Delhi
 - Tropical Weather Outlook
 - Tropical Cyclone Advisories
 - Tropical Cyclone Advisories for Civil Aviation
2. Bulletins issued by INOSHAC, Pune
 - Global Maritime Distress Safety System (GMDSS)
3. Bulletins issued by Cyclone Warning Division
 - Bulletin for India coasts
4. Bulletins issued by ACWCs/ CWCs
 - Four Stage Warning Bulletin
 - Sea Area Bulletin
 - Coastal Weather Bulletins
 - *Warnings to Ports*
 - Warnings for Fisheries
 - Bulletins for All India Radio (AIR)
 - Coastal Bulletins for AIR news cycle
 - Registered/designated warnees
 - Press Bulletins
 - Aviation Warnings
 - Bulletins for Indian Navy

6.2. Bulletins Issued by RSMC, New Delhi

The tropical weather outlook is issued once daily by RSMC, New Delhi throughout

the year under normal weather conditions based on 0300 UTC observations. An additional Special Tropical Weather outlook is issued again based on 1200 UTC observations when a depression is located over the north Indian Ocean region. When a system reaches the cyclonic storm stage, Cyclonic Storm Advisories will be issued at 00, 03, 06, 09, 12, 15, 18 and 21 UTC. Supplementary advisories may also be issued as necessitated by circumstances e.g., change in intensity or movement. The bulletins issued by RSMC, New Delhi are briefly described below:

6.2.1. Tropical Weather Outlook

Tropical Weather Outlook is issued daily at 0600 UTC based on 0300 UTC observations in normal weather for use of the member countries of WMO/ESCAP Panel. Description of Tropical Weather Outlook Bulletin contains the following

- convective activity;
- meteorological situation over the basin;
- observed lows;
- their potential of intensification at short range (risk for development of a depression (T 1.5) within the next 24 hours) or beyond.

A special weather outlook is issued at 1500 UTC based on 1200 UTC observations when a tropical depression lies over north Indian Ocean. The special tropical outlook indicates discussion on various diagnostic

and prognostic parameters apart from the 72 hours track and intensity forecast from the stage of deep depression. The track and intensity forecast are issued for +06, +12, +18, +24, +36, +48, +60 and +72 hours or till the system is likely to weaken into a low pressure area. It also includes the description of current location & intensity and past movement description of satellite imageries. The time of issue of this bulletin is HH+ 3 hours.

The Special Tropical Weather Outlook Bulletin, to be issued five times a day (based on 00, 03, 06, 12, 18 UTC) contains the following.

- Current location and intensity
- Past movement
- Convective activity ;
- T number, estimated central pressure and Maximum sustained surface wind (MSW)
- Sea condition
- 72 hrs (00, 06, 12, 18, 24, 36, 48, 60 and 72 hrs) forecast track, intensity and quadrant winds for thresholds of $\geq 28, 34, 50$ and 64 kts (Text and graph) from deep depression stage onwards till the weakening of the system.
- Storm surge guidance (if any)
- Meteorological situation over the basin (Diagnosis and prognosis)

6.2.2. Tropical Cyclone Advisories

Tropical cyclone advisories are issued at 3 hourly intervals based on 00, 03, 06, 09, 12, 15, 18 and 21 UTC observations. The time of issue is HH+03 hrs. Tropical cyclone advisories are transmitted to panel member Countries through global telecommunication system (GTS) and are also made available on real time basis through internet at IMD's website: <http://www.imd.gov.in>. and e-mail. RSMC, New Delhi can also be contacted through e-mail cwdhq2008@gmail.com) for any real time information on cyclonic disturbances over north India Ocean.

Tropical Cyclone Advisory Bulletin for Panel countries (RSMC Bulletin), contains the following.

- Current Location and Intensity
- Past movement
- Convective activity ;
- T number, estimated central pressure and Maximum sustained surface wind (MSW)
- Sea condition
- 72 hrs (00, 06, 12, 18, 24, 36, 48 and 72 hrs) forecast track, intensity and quadrant winds for thresholds of ≥ 28 , 34, 50 and 64 kts (Text and graph)
- Storm surge guidance (if any)
- Meteorological situation over the basin (Diagnosis and prognosis)
Format of Tropical Cyclone Advisory bulletin issued by RSMC is discussed on next page.

 UNCERTAINTY AND QUADRANT WIND DISTRIBUTION ARE GIVEN AS APPENDIX**

6.2.3. Tropical Cyclone Advisories for Civil Aviation

Tropical Cyclone Advisories for civil aviation are issued for international aviation as soon as any disturbance over the north Indian Ocean attains or likely to attain the intensity of cyclonic storm (sustained surface wind speed ≥ 34 knots) within next six hours. These bulletins are issued at six hourly intervals based on 00, 06, 12 and 18 UTC synoptic charts and the time of issue is HH+03 hrs. These bulletins contains present location of cyclone in lat./long., max sustained surface wind (in knots), direction of past movement and estimated central pressure, forecast position in Lat./

Long and forecast winds in knots valid at HH+6, HH+12, HH+18 and HH+24 hrs in coded form. The tropical cyclone advisories are transmitted on real time basis through GTS and AFTN channels to designated International Airports of the region prescribed by ICAO.

The Tropical cyclone advisory centre (TCAC) bulletin has following characteristics.

- It is a text cum graphical bulletin.
- Issued from cyclone stage till it weakens into a deep depression
- The format of bulletin is given below.

6.3. Global Maritime Distress Safety System (GMDSS)

Under Global Maritime Distress Safety System (GMDSS) scheme, India has been designated as one of the 16 services in the world for issuing Sea area bulletins for broadcast through GMDSS for MET AREA VIII (N), which covers a large portion of north Indian Ocean. As a routine, two GMDSS bulletins are issued at 0900 and 1800 UTC. During cyclone situations, additional bulletins (up to 4) are issued for GMDSS broadcast. The area of responsibility and designated National Meteorological Services for issue of weather and sea area bulletins is shown in Fig.6.1. List of stations issuing cyclone warnings for ships on the high seas is given in table 6.1.

6.3.1. Transmission of GMDSS bulletin

India is one of the issuing services of Met area VIII (N) among the 16 issuing services of WMO Marine broadcast system under the GMDSS. In India, the weather forecast and warning bulletin is prepared by ACWC (Area Cyclone Warning Centre) Mumbai for the Arabian Sea, by ACWC, Calcutta for the Bay of Bengal and INOSHAC (Indian Ocean & South Hemispheric Centre), Pune for Indian Ocean, North of equator upto 5°N, for their areas of responsibility. The bulletins are compiled by INOSHAC, Pune and transmitted to RSMC, New Delhi. RSMC, New Delhi edits the final bulletin if required and transmits to Tele-communication Division (Regional Telecommunication Hub (RTH), New Delhi)

for further transmission through local earth station (LES), Arvi as shown in Fig.6.2.

6.3.2. Frequency of Broadcasts

To start with as a routine only, one GMDSS bulletin for METAREA VIII (N) was broadcast at 0900 UTC. From October 1998, a second bulletin is also broadcast at 1800 UTC. During Cyclone situations, additional bulletins (up to 4) are also being issued for GMDSS broadcast depending on the requirement.

In addition, India is also issuing weather and warning bulletins to the NAVTEX transmitting stations located at Mumbai and Chennai.

6.3.3. Modality of Transfer of GMDSS Bulletin to CES ARVI

GMDSS BULLETIN is transferred to CES ARVI in manual mode using a dedicated telex terminal connected to the “store and forward switching computer” of the CES ARVI. The procedure involves dialing, login, entering C codes, Start of the message (BT), text and end of the message characters. On an average, it takes 5 minutes to transmit the message to CES ARVI at the normal telex speed of 50 baud. It takes another 2-3 minutes for the message to be received at the monitoring terminal to check its correctness and clarity.

The operational GMDSS broadcast is currently operating smoothly without any noticeable problems. The feedback response received from a few shipping companies are very encouraging.

Table 6.1. Stations issuing cyclone warnings for ships on the high seas

Station	Call sign of Coastal Area covered Radio Station	Area covered
Bangladesh , Chittagong	ASC	Bay of Bengal north of 18°N Lat.
India , Mumbai		Arabian Sea north of Lat. 5°N and east of Long. 60°E excluding the area north of Lat. 20°N and west of Long. 68°E. The eastern boundary of the Arabian Sea for which these bulletins are issued by Mumbai is Long. 80°E meridian excluding the Gulf of Mannar.
India , Kolkata		Bay of Bengal north of Lat. 5°N except the area between the coastline on the east and the line drawn through the points 18°N 94.5°E, 18°N 92°E, 13.5°N 92°E, 13.5°N 94°E, 10°N 94°E, 10°N 95°E and 5°N 95°E. The western boundary of the sea area for which bulletins are issued by Kolkata is up to and inclusive of the Gulf of Mannar (i.e., 77.5°E meridian).
*India , Chennai		Bay of Bengal bulletins issued by ACWC Kolkata are being broadcast through Navtex, Chennai by Narrow Band Direct Printing (NBDP)
Myanmar , Yangon	XYR	Bay of Bengal except area west of Long. 92°E and South of 10°N Lat.
Oman (Sultanate of)	A4M	Muscat Coastal Radio Station
**Pakistan , Karachi	ASK	Arabian Sea north of 20°N, Gulf of Oman and Persian Gulf.
Sri Lanka , Colombo	4PB	Indian Ocean, Arabian Sea and Bay of Bengal from the equator to 10°N between 60°E and 95°E. The area 5°N to 10°N between 60°E and 95°E is an overlap with India.
Thailand , Bangkok	HSA HSS	Gulf of Thailand, west of southern Thailand. Strait of Malacca and South China Sea.

* Under the new Marine Meteorological Broadcast system, GMDSS (Global Marine Distress Safety System) of IMO/WMO, India issues two bulletins at 0900 and 1800 UTC everyday for broadcast through INMARSAT SAFETY SYSTEM. Additional bulletins are broadcast during Cyclone period.

** To comply IMO/WMO GMDSS and marine Meteorological Broadcast System Pakistan issues the high seas forecast / Marine bulletins for met area-IX daily at 0700 UTC for broadcast through INMARSAT SAFETYNET SYSTEM. These bulletins are issued at 1900 UTC if so required.

6.4. Bulletin for India Coasts

6.4.1. Four Stage Warning Bulletin Issued by Cyclone Warning Division

Bulletin for India coast is issued in different stages as mentioned below.

- Pre-cyclone watch,
- Cyclone alert,
- Cyclone warning,
- Post landfall outlook
- De-warning

These bulletins are issued from the stage of depression onwards. During the stage of depression/deep depression; it is issued based on 00, 03, 06, 12, and 18 UTC observations. When the system intensifies into a cyclonic storm over north Indian Ocean, these bulletins are issued at 00, 03, 06, 09, 12, 15, 18 and 21 UTC (every

three hourly interval) based on previous observations. This bulletin contains present status of the system i.e. location, intensity; past movement and forecast intensity & movement for next 72 hours or till the system weaken into a low pressure area, likely landfall point & time and likely adverse weather including heavy rain, gale wind & storm surge. Expected damage and action suggested are also included in the bulletins. This bulletin is completely meant for national users.

At national level, cyclone warning is furnished on a real time basis to the Control Room in the Ministry of Home Affairs, Government of India, besides other Ministries & Departments of the Central Government. This Division provides cyclone warning bulletins to Doordarshan and All India Radio (AIR) at New Delhi for inclusion in the National broadcast/telecast. Bulletins are also provided to other electronic and print media and concerned state Governments.

Different colour codes are being used since post monsoon season of 2006 at different stages of the cyclone warning bulletins (cyclone alert-yellow, cyclone warning-orange and post landfall outlook-red), as desired by the National Disaster Management.

Description of this bulletin contains the following:

- Date and time of issue
- Current Location and Intensity
- Past movement
- Maximum sustained surface wind (MSW)

- 72 hrs (00, 06, 12, 18, 24, 36, 48 and 72 hrs) forecast track and intensity (Text and graph) from deep depression stage onwards till the weakening of the system.
- Forecast track and intensity as mentioned above.
- Adverse weather (Text and graph)
- Advisory and action suggested
- Time of issue of next bulletin

In case of depression, only plain language forecast will be given without the quantitative 72 hr forecast track and intensity as mentioned above.

6.4.2. DGM's Bulletin for High Govt. Officials

DGM's Bulletin for high Govt officials is issued as follows.

- It is issued once a day.
- It summarises past 24 hrs development in terms of track and intensity.
- It contains past 24 hrs weather
- Other contents are same as that of bulletin for India coast as discussed in Sec.6.3.1

The format of this bulletin is same as the format of 'Bulletin for India coast incorporating all the above features.

6.4.3. Bulletin Through SMS

The bulletins are sent through various national disaster management agencies and the concerned chief secretary of the likely to be affected states in case of a landfalling cyclone.

QUADRANT WIND DISTRIBUTION ARE GIVEN AS APPENDIX**

6.4.4. Personal Briefing

At the national level, the personal briefings are provided by Cyclone Warning Division to national disaster management agencies including cabinet secretariat, MHA, NDRF and NDMA and press and electronic media.

6.4.5. Press Conference

A press conference is held under the chairmanship of Director General of Meteorology, IMD at New Delhi well in advance for the press and electronic media. All the details about the cyclonic storm and associated adverse weather, likely impact and action suggested to public and disaster management agencies are provided in this conference

6.5. User Specific Bulletins Issued by ACWCs/CWCs

The ACWCs/CWCs issue warnings to ships in the high seas, ships in coastal waters, ports, fishermen, government officials and the general public regarding adverse weather likely to be experienced in their respective areas. The bulletins and warnings issued by ACWCs/CWCs for their respective areas of responsibility include

- Four stage warning bulletin
- Sea area bulletins for ships plying in High Seas
- Coastal weather bulletins for ships plying in coastal waters

- Bulletins for Indian Navy
- Port Warnings
- Fisheries Warnings
- Four stage warnings for Central and State Govt. Officials
- Bulletins for broadcast through AIRs for general public
- Warning for registered users
- Bulletins for press
- Warnings for Aviation (issued by concerned Aviation Meteorological Offices)

6.5.1. Four Stage Warning Bulletin

The most important warning for disaster management is the one issued to government officials under a four-stage warning system. The **First Stage** warning known as “**PRE CYCLONE WATCH**” issued 72 hours in advance of commencement of adverse weather contains early warning about the development of a cyclonic disturbance in the NIO, its likely intensification into a TC and the coastal belt likely to experience adverse weather. The **Second Stage** warning known as “**CYCLONE ALERT**” is issued at least 48 hrs in advance of the expected commencement of adverse weather over the coastal areas. It contains information on the location and intensity of the storm, likely direction of its movement, intensification, coastal districts likely to experience adverse weather and advice

to fishermen, general public, media and disaster managers. The **Third Stage** warning known as “**CYCLONE WARNING**” is issued at least 24 hours in advance of the expected commencement of adverse weather over the coastal areas. These warnings give the latest position of cyclone and its intensity, likely point and time of landfall, associated heavy rainfall, strong wind and storm surge along with their impact and advice to general public, media, fishermen and disaster managers. The **Fourth Stage** of warning known as “**POST LANDFALL OUTLOOK**” is issued at least 12 hours in advance of expected time of landfall. It gives likely direction of movement of the cyclone after its landfall and adverse weather likely to be experienced in the interior areas. All the above warnings are issued by ACWCs/ CWCs/and CWD. Format for Alert/Warning bulletin and Post Landfall Outlook are shown below:

**Format for State/Central Govt. Officials/

(d) Rail & road transport to be
regulated.

FORMAT FOR POST LANDFALL OUTLOOK

(To be appended at the end of the Cyclone Bulletin issued 12 hrs before estimated landfall time)

POST LANDFALL OUTLOOK FOR MCs/ RMCs

Even after landfall, the system is likely to maintain its intensity for Hours and weaken gradually AAA Under its influence, rains at most/many places with heavy to very heavy falls at likely to commence/continue in (coastal districts) from (time)..... (day) (dates) causing inundation of low-lying areas AAA Gale winds/squally winds speed reaching kmph likely commence/continue in (coastal districts) from(time) on.....(day)..... (date) causing damages to (property as indicated in IMD monograph on "DAMAGE POTENTIAL OF TROPICAL CYCLONE") and (vegetation) and general disruption of communication and power supply for

2. As the cyclone moves inland Interior districts may also experience heavy/very heavy

rain accompanied with gale with speed reaching kmph commencing from (time) on (day) (date) for hrs, causing flooding of low lying areas and damage to property as indicated in IMD monograph on "DAMAGE POTENTIAL OF TROPICAL CYCLONE" (as per IMD instruction)

3. People are advised to remain indoors/ in safe places and cooperate with state government officials and disaster management agencies.

6.5.2. Sea Area Bulletin

Sea area bulletins for Bay of Bengal are issued by ACWC Kolkata and are broadcast by the coastal radio stations at Kolkata (VWC) and Chennai (VWM) and those for Arabian Sea are issued by ACWC Mumbai and are broadcast by the coastal radio station at Mumbai (VWB). The area covered by these bulletins which is the area of responsibility assigned to India by the World Meteorological Organisation (WMO), is shown in Fig.6.3.

During undisturbed weather, only two bulletins are issued per day, known as Daily bulletins. In the event of disturbed weather, a third bulletin known as extra is broadcast, if considered necessary. However, when a depression has actually formed, the Extra bulletin must be issued. When a cyclonic storm has developed,

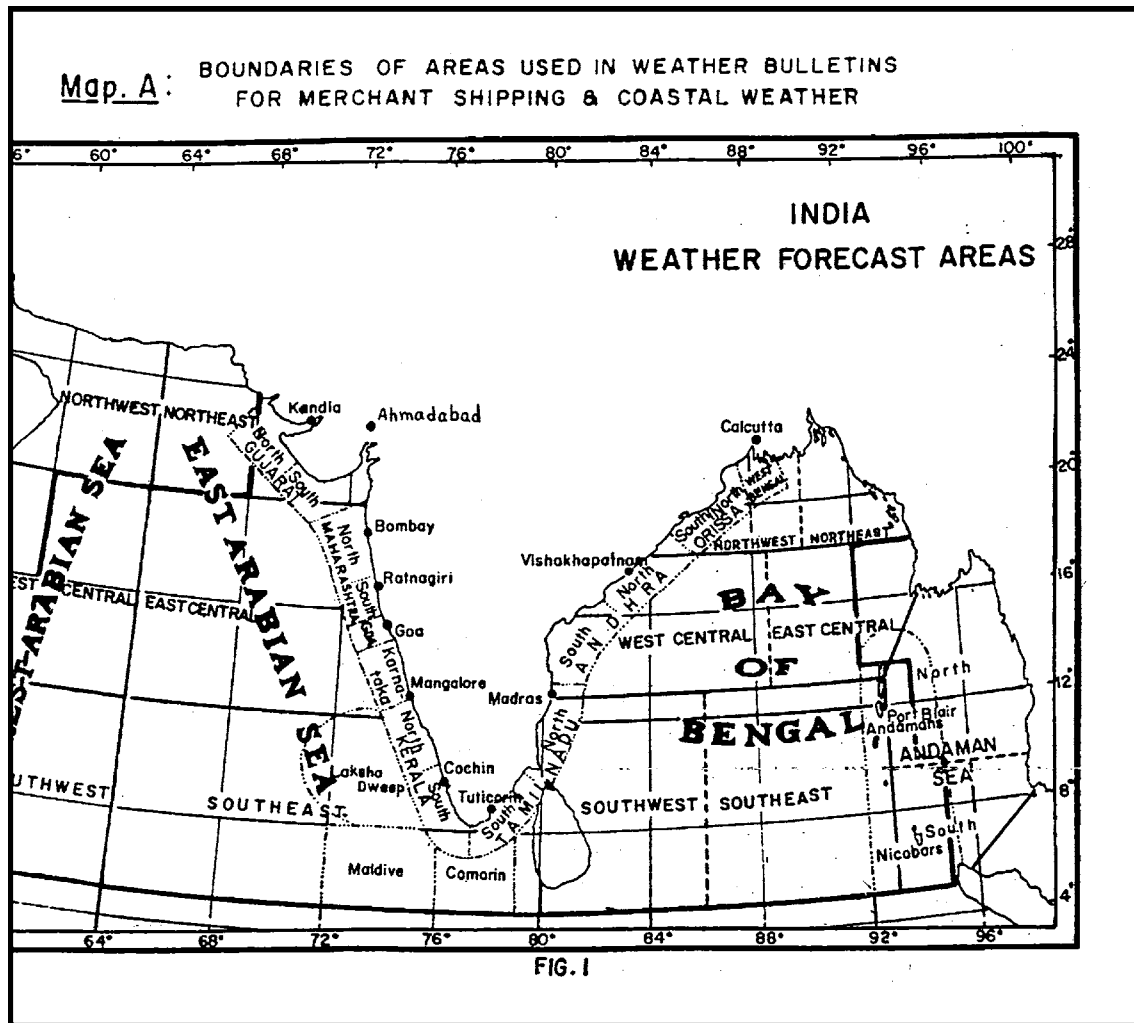

Fig. 6.3. Area of coverage for issue of coastal weather bulletin and sea area bulletin

every attempt should be made to broadcast three additional bulletins a day. The three additional bulletins are known as Storm bulletins which together with the three bulletins mentioned earlier, make up a total of six bulletins a day. Storm three i.e. GASBAG bulletin (1500 UTC) should be issued on routine basis during cyclone situation. These bulletins are broadcast at fixed hours according to a schedule. In addition, if any unexpected

development of weather warrants urgent communication to ships, in between scheduled broadcasts, it is broadcast in the form of a special bulletin, called Hexagon which should be issued immediately after the development is noticed. A code word (which is not for broadcast) is prefixed to each of the bulletins as a preamble for easy identification by the coastal radio stations on receipt. These are given in the table 6.2.

Table 6.2. Prefix of Code Word to Sea Area Bulletin for coastal Radio Stations

Code word	Type of bulletin	Chart on which based (UTC)
ELECTRON	Storm-One	0000
AURORA	Daily-One	0300
FORMULA	Storm-Two	0900
BALLOON	Daily-Two	1200
GASBAG	Storm-Three	1500
DEW DROP	Extra	1800
HEXAGON	Special	Anytime

Format of 'daily' bulletin

The formats for the three messages are as follows:

- i) Aurora/ Balloon OBS Date.....
Part One etc..... Part Two etc.
.....
- ii) OBS Date..... Part Three Area Forecast
etc. Part Four Analysis etc.
.....
- iii) OBS Date ...Part Five Ships' Broadcast
etc.Part Six 0300 Z synop etc.
...

In case of 'extra', 'storm' and 'special' type, bulletin consists of only Part I

Format of Part – I

When a depression or a cyclonic storm has formed or is expected to form or when gales are expected, Part I of the bulletin will contain the following items in the order mentioned below:

- (1) International Safety Call sign (TTT).
- (2) Statement of type of warning (Warning, gale warning, cyclone warning etc.)
- (3) Date and time of reference in UTC in the international six figure date-time group.
- (4) Type of disturbance (low, when it is expected to intensify into a depression before broadcast of the next bulletin, depression, monsoon gale, cyclonic storm etc.) with central pressure in hPa in the case of disturbances of cyclonic storm intensity and above.
- (5) Location of disturbance in terms of latitude and longitude.
- (6) Direction and speed of movement of disturbance. (The direction may be given in 16 points of compass or in degrees to the nearest ten; the speed is given in knots.) The departmental practice is to give the direction in sixteen points of the compass.
- (7) Extent of area affected.
- (8) Speed and direction of wind in various sections of the affected area. (Wind speeds are given, if possible, for different distances from the centre, in different sectors of the storm area. Wind speeds are given in knots and distances in nautical miles.)
- (9) Further indications, if any

Contents of Part-II

When there is no warning in the area, Part I in the Daily bulletin contains the words *No storm warning*. In Part II, Weather is characterized as *Seasonal* when there is no synoptic system in the area. However, during the monsoon season, the strength of the monsoon is described according to corresponding wind speed over the area.

Contents of Part III:

Part III contains a forecast of (i) weather, (ii) wind and (iii) visibility. The period of validity of the forecast should be till the broadcast time of the next routine *Daily One* or *Two* bulletins. The message should begin with a preamble on the period of validity of the forecast, which will be indicated by the phrase *Forecast valid till UTC of (date)*. Forecast of weather (such as rain, rainsqualls, thunderstorms etc.) is given only for areas over which it is expected to occur. No forecast is included for areas where no weather is expected. Wind direction is given in eight points of the compass and the wind speed in knots.

Contents of Part IV

Part IV of the bulletin contains surface analysis encoded in the abridged form of the International Analysis Code for marine use (IAC FLEET) and includes essential isobars. ACWC Mumbai issues analysis for the area from Lat. 5° – 25° N and Long 60° – 80° E and ACWC Kolkata for the area from Lat. 5° – 30° N and Long. 75° – 100° E.

Part V

Data of observations from ships in WMO codes.

Part VI

Data of observations from selected land stations and upper air reports in WMO codes.

6.5.3. Coastal Weather Bulletins

These bulletins are meant for ships plying in coastal waters. These are for the benefit of ships sailing close to the coast and are issued by the ACWCs Kolkata, Chennai, Mumbai and CWCs Visakhapatnam, Bhubaneswar, and Ahmedabad for the different coastal areas (Fig.6.3) under their responsibility. These bulletins are broadcast in Morse code as well as by NAVTEX stations in plain language from the 11 coastal DOT radio stations – 6 on the west coast, 4 on the east coast and 1 in Andaman and Nicobar Islands. From CWC Ahmedabad, coastal bulletins are issued twice daily to ACWC Mumbai and Mumbai Radio for both South Gujarat and North Gujarat coast. Similarly, CWC Bhubaneswar and Visakhapatnam send the bulletins to ACWC, Kolkata/ Kolkata Radio and ACWC, Chennai/ Chennai Radio respectively. The format of Coastal Weather Bulletin is given below. As in the case of sea area bulletins, the coastal weather bulletin is issued twice daily based on 03 & 12 UTC in normal weather, thrice a day based on 03, 12 & 18 UTC in case of depression/deep depression stage and

5/6 times a day at 00, 03, 06, 09, 12 & 21 UTC in cyclone stage. In undisturbed weather, the two bulletins issued are based on 0300 and 1200 UTC charts and they are called Daily One and Daily Two, corresponding to Aurora and Balloon sea area bulletins. However, during periods of disturbed weather, when Extra, Storm or Special sea area bulletins are issued, corresponding coastal bulletins are also to be issued for the particular coast which is likely to be affected, necessitating the hoisting of signals of LC-III and above at the ports. If local weather along a coast is not affected by the disturbance, additional coastal bulletins for the coast need not be issued. Each bulletin (*Daily*, *Extra*, *Storm* and *Special*) contains the following information in the order given below :

- (1) Name of coastal Strip
- (2) Synoptic system, if any, affecting the weather over the coastal strip and its movement in the case of depressions and cyclonic storms.
- (3) Period of validity of forecast.

- (4) Forecast of wind, weather, visibility and state of sea for the coastal strip.
- (5) Information about storm warning signals, if any, hoisted at ports on the coastal strip concerned.
- (6) Information on storm surges/tidal waves (whenever necessary).

6.5.4. Fleet Forecast for Indian Navy

Since Naval ships normally do not keep watch on commercial W/T wavelengths and hence do not listen to the broadcasts from the coastal radio stations, separate weather bulletins for broadcast to the ships of the Indian Navy are issued to the Naval W/T stations. The bulletins that are issued exclusively for broadcast to Indian Naval ships are called the Fleet Forecasts. Fleet Forecasts are issued exclusively for broadcast to Indian Naval ships through Naval W/T stations. They are issued twice daily, corresponding to *Aurora* and *Balloon* sea area bulletins. The offices which issue the Fleet forecasts and their areas of responsibility are shown in Fig. 6.4 and Table 6.3.

Table 6.3. Area of responsibility for fleet forecast

S. No.	Office of issue	Area of responsibility	Sub-areas
1.	ACWC Mumbai	Arabian Sea to the north of Lat. 5°N and East of Long.60°E, Gulf of Oman and Persian Gulf	B 00, 20, 25, 30, 35, 40, 55 & E 00, 05
2.	ACWC Kolkata	Bay of Bengal and Andaman Sea to the north of Lat. 5°N	C 65, 70, 75, 80, 85 E10 and West half of E 15.
3.	INOSHAC, Pune	Indian Ocean between Lat.5°N and 10°S and Long.60°E and 100°E	E 20, 25, 30, 35, 40,45, 50, 55, 60, 65, 70,75.

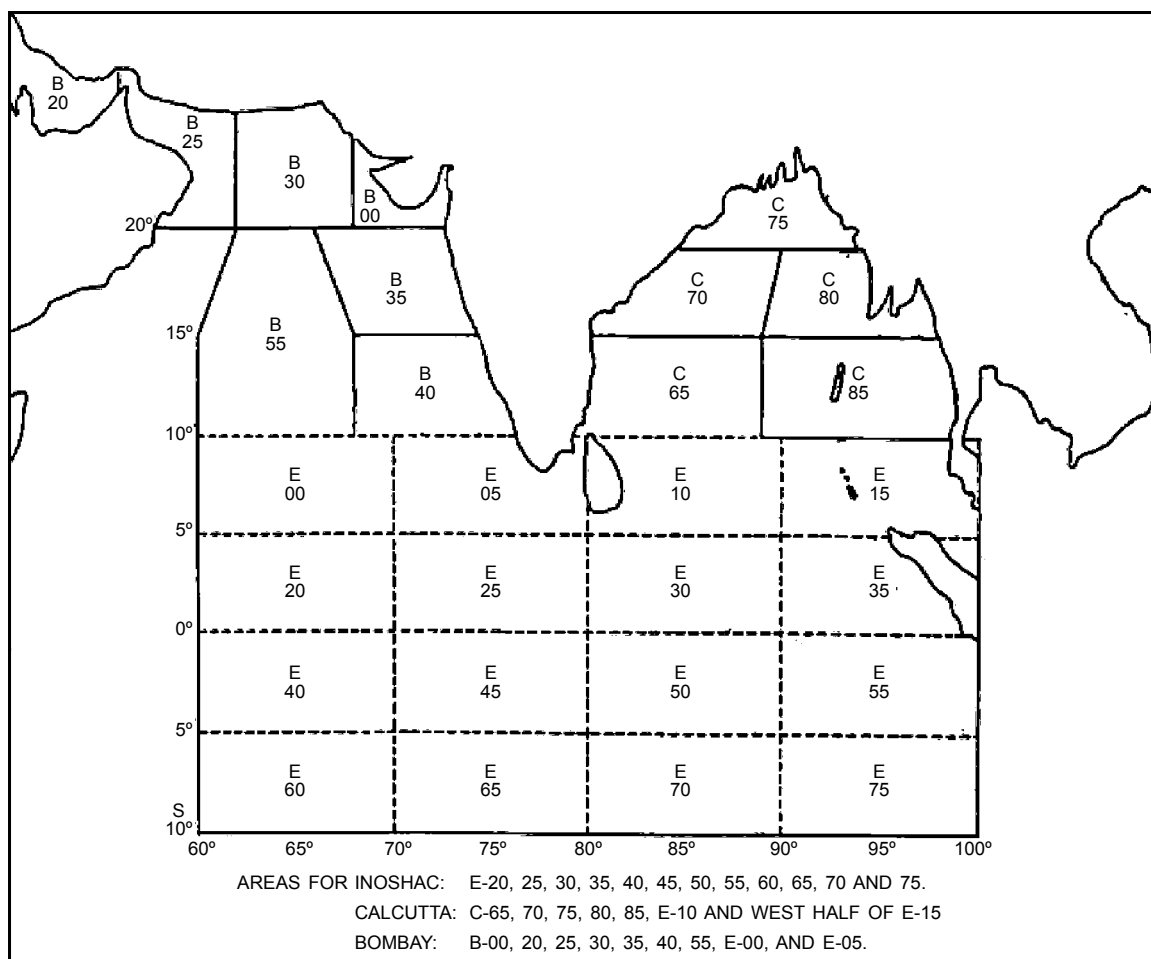

Fig. 6.4. Map showing areas for fleet forecast issued by IMD

6.5.4.1. Items in Fleet Forecast

The Fleet Forecast is in plain language and contains a brief general inference for the area including warnings. In the case of Bay of Bengal and Arabian Sea, the inference will conform to the *Aurora* and *Balloon* bulletins issued by ACWCs Mumbai and Kolkata. The forecast covers surface wind, visibility and state of sea and an *outlook* for the next 12 hours. Fixed times of origin are given to the Fleet Forecast messages – 0800 UTC in

the case of day bulletin and 1700 UTC in the case of the night bulletin. These Fleet forecasts are broadcast by Naval W/T station, Mumbai, during weather broadcast periods commencing from 0930 UTC and 1830 UTC respectively. Fleet Forecast messages should be brief with the view that the requirements of ships at sea are principally wind (direction and speed) and visibility and hence the area forecasts must contain only these two elements and their variations. The central pressure is given

from Storm stage upwards. The two daily forecasts are valid for 12 hours from 1000 UTC and 2200 UTC respectively. Outlook for next 12 hours in clear terms from the termination of the forecast period should be appended to both day and night bulletins as a routine. When weather conditions are reasonably stable, the evening forecast may be abbreviated with reference to the previous morning forecast.

6.5.4.2. Mode of Transmission of Fleet Forecast to Naval W/T Mumbai

ACWC Kolkata and INOSHAC Pune send their Fleet Forecasts to RCC Mumbai through Departmental telecommunication channels. These Fleet Forecasts together with the one issued by ACWC Mumbai are transmitted to Naval W/T Station, Mumbai, through the Naval Met.Office, Mumbai.

6.5.5. Warnings to Ports

6.5.5.1. Hoisting of Signals

A uniform system of storm warning signals was introduced at all the ports in India from 1st April 1898 and it is still in vogue with very little changes. The salient features of the system are described below :

(i) General System

A General System with eleven signals (Table 6.4), the first two of which (signals No. I and II) indicate the existence of distant disturbed weather, the next eight (signals III to X) indicate that the port

itself is threatened by bad weather and the last one (signal No. XI) indicates that the communication with the ACWC/CWC had broken down and that in the opinion of the local Port Officer, there is danger of bad weather. Signals No. I and II are called Distant Signals and the rest Local signals. The ports where this system of signals is in use are called General Ports.

(ii) Extended System

An Extended System which in addition to the eleven signals of the General System, has six Section signals (Details are given in Cyclone Manual) to indicate the location of the disturbance. These additional signals are hoisted along with Distant Signals. This system is a special case of the General System and is in use only at a few ports on the east coast (Bay of Bengal). These ports are: Sagar Island, Kakinada, Chennai, Cuddalore and Nagapattinam. These ports are called Extended Ports. There is no port under the Extended System on the west coast.

(iii) Brief System

A Brief Systems consisting of only five of the signals of the General Systems (viz. Signal Nos. III, IV, VII, X and XI). These are hoisted in association with prospects of bad weather at the port itself caused by disturbances out at sea. This system of signals is in use in ports frequented mainly by smaller vessels engaged in local traffic and these ports are called Brief Ports.

Table 6.4. Port Warning Signals (General System) used in India

Signal/ Flag No.		NAME	Symbols		Description
			Day	Night	
1	DISTANT BAD WEATHER	DC1			Depression far at sea. Port NOT affected.
2		DW2			Cyclone far at sea. Warning for vessels leaving port.
3	LOCAL BAD WEATHER	LC3			Port Threatened by local bad weather like squally winds.
4		LW4			Cyclone at sea. Likely to affect the port later.
5	DANGER	D5			Cyclone likely to cross coast keeping port to its left.
6.		D6			Cyclone likely to cross coast keeping port to its right.
7.		D7			Cyclone likely to cross coast over/ near to the port.
8.	GREAT DANGER	GD8			Severe cyclone to cross coast keeping port to its left.
9.		GD9			Severe cyclone to cross coast keeping port to its right.
10.		GD10			Severe cyclone to cross coast over or very near to the port.
11.		XI			Communication failed with cyclone warning office.

(iv) Ports without Signals

In addition, there are some minor ports where no signals are hoisted but which get a special type of warning message; they are called Ports without signals. For purposes of warning, these ports are treated as Brief ports and corresponding port warnings are issued when adverse weather threatens them although no signals are advised to be hoisted. These warning messages will contain information on the location, intensity and direction of movement of the disturbance and the expected weather over the port.

The India Meteorological Department (through the ACWCs/CWCs) maintains a port warning service by which the port officers are warned by telefax about disturbed weather likely to affect their ports. On receipt of the warning bulletin from the ACWC/CWC, the port officers hoist appropriate visual signals prominently on signal masts so that they are visible from a distance. Mariners and other sea-faring people, including fishermen who may not be literate, are generally aware of the meaning of these signals and the port authorities are always ready to explain them whenever necessary. At some ports, the meanings of the signals are displayed in English as well as in the local languages prominently on a notice board. While the India Meteorological Department is responsible for issuing the warnings, the port authorities arrange the display of signals. In addition to hoisting

the signals, the port officers in most cases, make arrangements for disseminating the warnings received by them, to country craft and sailing vessels in the harbours. The port warning signals (general system) used in India are shown in Table 6.4

6.5.5.2. Frequency of Issue and Contents of Port Warning Bulletin

Ports in the maritime States are warned 5 to 6 times a day during periods of cyclonic storm by telefax. The warnings contain information about the location, intensity and expected direction of movement of the storm or depression, the part of the coast where it is expected to strike and the type of signal which the port should hoist. As landline communication between the port and the CWC may break down during a cyclone, provision exists for using state and inter-state police W/T channels wherever available for passing on the warnings.

6.5.5.3. Format for Port Warning

Port Warning No.

Date and Time for Issue

(i) Information on cyclone: The cyclonic storm lay over Bay of Bengal/Arabian Sea near Lat._____/Long. _____ at a distance _____ km. from _____ at _____ IST _____ Estimated Central Pressure _____ hPa.

(ii) Forecast:

Further intensification:

Direction of Movement:

Expected Landfall Area :

Expected Time of Landfall :

Advice for hoisting Storm Warning Signals:

Likely impacts and actions : Depending on intensity of the storm as per IMD Monograph on “Damage Potential of Tropical cyclones.

6.5.6. Warnings for Fisheries

6.5.6.1. Criteria for Warnings

Warnings for fishing interests are issued by the ACWCs/CWCs whenever the wind speed is expected to exceed 45 kmph (i.e. for squally weather, gales, strong monsoon and off shore winds) and state of sea very rough or above. These warnings are transmitted by landline telegram or over telephone to the AIR stations (about 30 in number) in the maritime states. These warnings are broadcast as a routine four times a day (morning, mid-day, evening and night) from the AIR stations in the local language. During a cyclonic storm, such warnings are covered in the cyclone bulletins sent to the AIR stations at hourly or 3 hourly intervals for frequent broadcast. The fishermen can listen to these broadcasts through portable radio receiving sets.

6.5.6.2. Warnings through FAX

In addition to warnings broadcast by AIR stations, direct warning messages are also

sent by telefax to a large number of officials belonging to the fisheries departments in maritime states.

6.5.6.3. Format for Fisheries Warning

Fisheries warning No. _____

Date and Time of Issue _____

Information on Cyclone:

Cyclonic Storm lay over _____

Bay of Bengal / Arabian Sea at a distance

_____ kms. _____

from _____ at _____ IST on

_____ (date)

Forecast:

Further intensification

Direction of Movement

Expected landfall area

Expected time of landfall

Warnings : Wind, Sea Condition and Tidal Waves

Storm Warning Signals at ports

Advice and Action:

- i) Fishermen not to venture into open seas
- ii) Fishermen at Sea not to come to the ports (names)_____ in coast.
- iii) Fishermen to be cautious while going out in the sea
- iv) Fishermen are advised to return to coast

6.5.7. Bulletins for All India Radio (AIR)

The cyclone warnings are also broadcast through AIR stations. After issuing the *Cyclone Alert* to the Chief Secretary and Collectors by FAX/mobile, the *Cyclone Warning* is also passed on to the concerned AIR stations for broadcast. In the *Cyclone Alert* message, the recipients are informed that the subsequent cyclone warnings will be broadcast from the concerned AIR station. When the cyclone is beyond the range of the coastal cyclone detection radar, that is, more than 400 km away from the coast, cyclone warnings are issued 6 times a day to the AIR stations and each warning is broadcast at frequent intervals interrupting the routine programme. When the cyclone comes within the radar range and is tracked by the radar hour to hour, cyclone warnings are issued every hour to AIR stations. During cyclone periods, the concerned AIR stations keep round the clock watch for broadcasting cyclone warnings.

6.5.7.1. Format for Cyclone Alert/Warning Bulletin for AIR/Press/Public :

Cyclone Alert / Warning Bulletin No. _____ issued by _____ at _____ Hrs. IST on _____ (Date) for repeated broadcast at hourly / half hourly intervals. Cyclone Alert / Warning for _____ Districts. Cyclone centred at _____ hrs. IST of _____ (date) about _____ kms. _____ of (direction) _____ (Place). Expected to

intensify further and move in a _____ direction and cross _____ coast near / between _____ (Place) _____ (day/time). Under its influence heavy to very heavy rain likely cause floods in _____ districts commencing from _____ (time/day). Gales speed reaching _____ kmph causing _____ damage _____ in districts commencing from _____ (Date/Time) Gale force winds reaching 70 kmph likely extend into _____ Districts, causing damage _____ in _____ districts. Tidal wave of _____ m Likely inundate low lying area of _____ Districts at the time of crossing coast.

Advice to Fishermen :

Public advised to cooperate with the State authorities in disaster management efforts.

6.5.8. Coastal Bulletins for AIR News Cycle

In addition, arrangement has also been made with AIR New Delhi for broadcast of coastal weather bulletins for the different coastal belts, in Hindi, English and the local languages in the AIR news cycles three times a day, viz., in the morning, mid-day and at night. These bulletins contain information on the location, intensity and expected direction of movement of the cyclone, state of sea off the coast and expected adverse weather (heavy rain, gales and tidal waves) in the coastal districts.

6.5.9. Registered/Designated Warnees

Warnings for heavy rain and gales are also issued by FAX/ e-mail/mobile to officers of the Revenue, P.W.D., Irrigation and Highways, DOT., Railways etc., who are on the warning list of the ACWCs/CWCs. For Andhra Pradesh, CWC Visakhapatnam gives these warnings from depression stage while MC Hyderabad issues during other periods. In addition, the warnings are kept in the Website for information.

6.5.10. Press Bulletins

Special press bulletins are issued during periods of cyclonic storms to local newspapers for giving publicity to the warnings.

6.5.11. Aviation Warnings

Warnings for airports and flight operations likely to be affected by tropical cyclones are issued by the concerned Aviation Meteorological Offices.

6.5.12. Bulletin through Satellite Based Cyclone Warning Dissemination System (CWDS)

For quick dissemination of warning against impending disaster from approaching cyclones, IMD has installed specially designed receivers within the vulnerable coastal areas for transmission of warnings to the concerned officials and people using broadcast capacity of INSAT satellite. This is a direct broadcast service of cyclone warning in the regional languages meant for the areas affected or likely to be affected

by the cyclone. There are 352 Cyclone Warning Dissemination System (CWDS) stations along the Indian coast; out of these 101 digital CWDS are located along Andhra coast. The IMD's Area Cyclone Warning Centres (ACWCs) at Chennai, Mumbai & Kolkata and Cyclone Warning Centre (CWCs) at Bhubaneswar, Visakhapatnam & Ahmedabad are responsible for originating and disseminating the cyclone warnings through CWDS. The bulletins are generated and transmitted every hour in three languages viz English, Hindi and regional language. The cyclone warning bulletin is up-linked to the INSAT in C band. For this service, the frequency of transmission from ground to satellite (uplink) is 5859.225 MHz and downlink is at 2559.225 MHz. The warning is selective and will be received only by the affected or likely to be affected stations. The service is unique in the world and helps the public in general and the administration, in particular, during the cyclone season. It is a very useful system and has saved millions of lives and enormous amount of property from the fury of cyclones. The digital CWDS have shown good results and working satisfactorily.

6.5.13. Personal Briefing

In addition to the FAX message, the Chief Secretary of the concerned state is also kept informed over telephone/mobile/fax/internet by the ACWC/CWC about the location, movement and intensity of the storm and the areas expected to experience severe weather.

6.5.14. Bulletin through SMS

The bulletins are sent through SMS to various state disaster management agencies and the chief secretary, relief commissioner etc in case of a landfalling cyclone.

6.6. Other Products Generated by Cyclone Warning Division, New Delhi

Following graphical products are developed every six hours based on 00, 06, 12 & 18

UTC by the CWD and sent to users. These products are also uploaded on the cyclone page of IMD website. The examples of these products are shown in Fig.6.5-6.8.

- (i) Past and 72 hrs (00, 06, 12, 18, 24, 36, 48 and 72 hrs) forecast track and intensity with cone of uncertainty
- (ii) Past and 72 hrs (00, 06, 12, 18, 24, 36, 48 and 72 hrs) forecast track with quadrant winds
- (iii) TCAC bulletin in graphical format
- (iv) Storm surge guidance
- (v) Adverse weather warning graphics

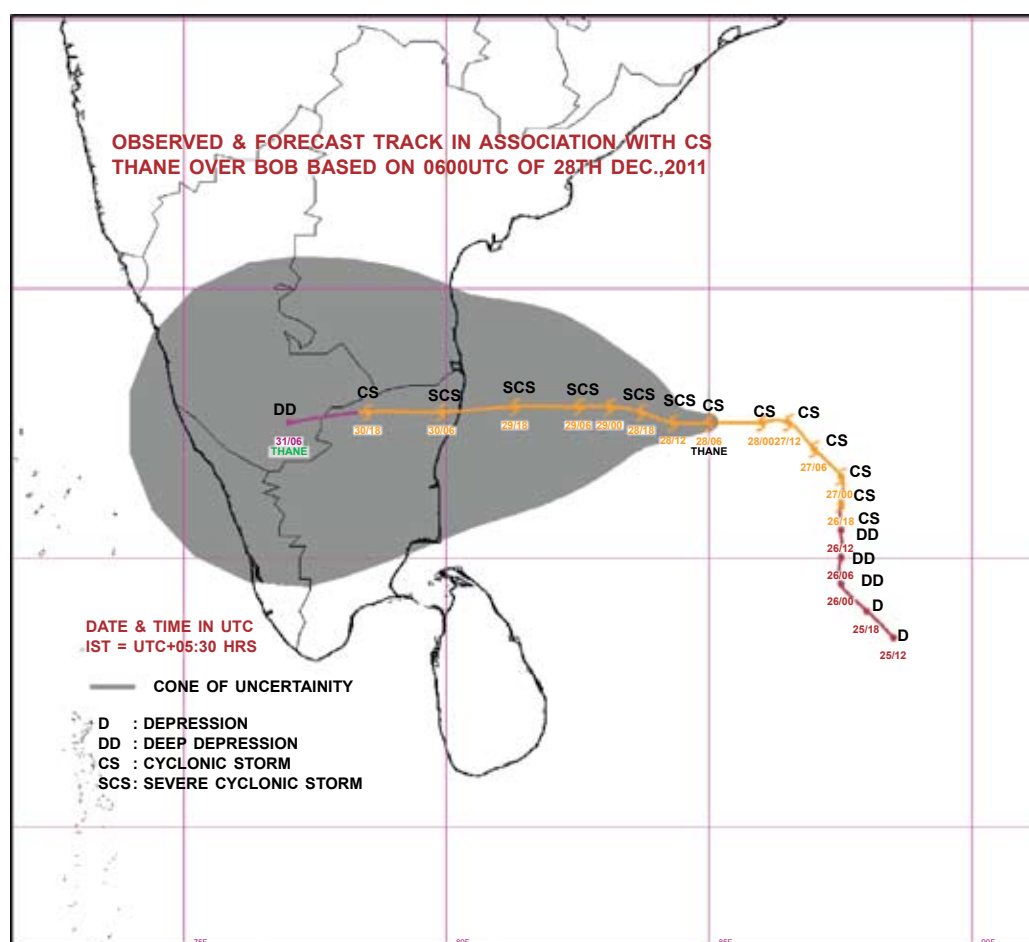

Fig. 6.5. Typical example of track alongwith cone of uncertainty forecast issued by IMD

6.6.1. Track and Cone of Uncertainty

Cone of Uncertainty has been introduced since Dec 2009, with effect from cyclone, WARD. It is based on the standard errors of last five years of different forecast periods. The standard errors are given in table 6.5 and an example of the uncertainty forecast is shown in the Fig. 6.5. The standard error for a given forecast time is considered as radius of the circle (R) with forecast latitude & longitude point as the centre of the circle. The cone of uncertainty is the tangent line constructed from the circles drawn for all forecast points.

Table 6.5. Radius of circle to construct cone of uncertainty

F/C Period	Radius of the circle to construct cone of uncertainty (km/nm)
12 hr	75/40
24 hr	150/80
36 hr	200/105
48 hr	250/135
60 hr	300/165
72 hr	350/190
96 hr	450/245
120 hr	550/300

6.6.2. Ship Avoidance Guidance

Radius of circle to construct the area of ship avoidance guidance is given in Table 6.6. The radius of this circle is the combination of radius of cone of uncertainty and the radius of gale wind (34 kts or more).

Table 6.6. Radius of circle to construct the cone of ship avoidance guidance

F/C Period	Radius (km/nm) of circle to construct cone of ship avoidance
12 hr	Radius of 34 kts wind + 75/40
24 hr	Radius of 34 kts wind + 150/80
36 hr	Radius of 34 kts wind + 200/105
48 hr	Radius of 34 kts wind + 250/135
60 hr	Radius of 34 kts wind + 300/165
72 hr	Radius of 34 kts wind + 350/190

6.6.3 Tropical Cyclone (TC) Vitals

The TC vital contains the vital components required to describe a TC. It contains the location, intensity, radius of maximum wind, radii of 28, 34, 50 and 60 knots wind threshold in four different quadrants of the system (northeast, northwest, southeast and southwest) at the initial state and forecast states upto 72 hrs. The quadrant wind forecast is issued from the deep depression stage only and when the system is over sea. Issued 4 times a day based on 00, 06, 12 and 18 UTC observation and analyses. It is issued within 3 hrs of time of observation.

6.6.3.1. Format of TC Vitals

QUADRANT WIND DISTRIBUTION IN ASSOCIATION WITH _____ (Name of the system) over _____ (area and basin)
 DATE AND TIME BASED UPON WHICH FORECAST IS PREPARED:
 PRESENT DATE AND TIME: _____ UTC

PRESENT POSITION: _ _ .°N/ _ _ .° E

POSITION ACCURATE TO 50 KM

- NM NORTHWEST QUADRANT

Forecast is similarly prepared for 12, 18, 24, 36, 48, 60 and 72 hrs. A graphics version of this bulletin is also prepared and sent to users as well as put up in website. A typical example is shown in Fig.6.6.

6.6.4. Storm Surge Warning

In the bulletin for India coast storm surge guidance is provided. It depicts the height of storm surge expected above the astronomical tide along the coast. Storm surge guidance for WMO/ESCAP Panel countries is being issued as and when necessary from April, 2009 onwards as per their requirement. It is added in the Tropical Cyclone Advisory Bulletin for WMO/ESCAP Panel Member countries. An example of storm surge guidance based on IIT, Delhi model is shown in Fig.6.7.

The storm surge guidance is provided in both text and graphic format. The guidance in text form is added in the bulletin for India coast. The storm surge warning in graphics is uploaded in website of IMD.

6.6.5. Heavy Rainfall Warning

In the bulletin for India coast heavy rainfall warning is provided. It describes the area of occurrence, time of occurrence and intensity of heavy rainfall. The heavy rainfall is provided in three categories, viz., heavy rainfall (7-12 cm), very heavy rainfall (13-24 cm) and extremely heavy rainfall (25 cm or more) expected in next 24 hrs. A graphical product is also given indicating the heavy rainfall warning. An example of heavy rainfall warning graphics is shown

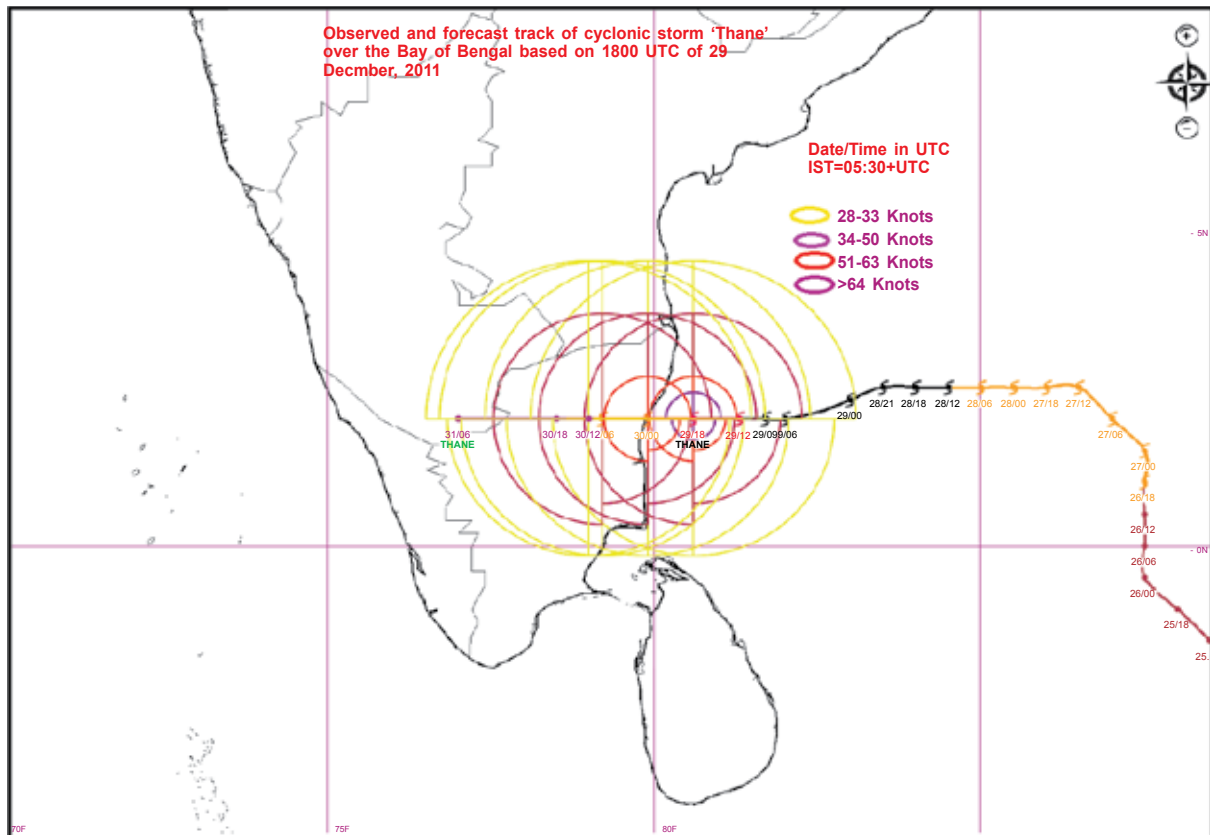

Fig. 6.6. Typical example of radii of quadrant wind forecast issued by IMD

Surge contour (m)-2009 Aila cyclone (RSMC Track)

Fig. 6.7. Storm surge guidance during cyclone AILA

in Fig.6.8. This product is available in website of IMD.

6.6.6. Gale Wind Warning

In the bulletin for India coast gale wind warning is provided. It describes the area of occurrence, time of occurrence and intensity of gale/squally wind along and off coastal districts. Depending upon the expected gale wind speed, the expected damage is indicated in the bulletin.

6.6.7. Crucial Observations

Crucial observations leading to decision of location and intensity is also mentioned in the bulletin issued for WMO ESCAP Panel countries.

6.6.8. Satellite and Radar Features

The characteristic features as observed in satellite and radar are included in the bulletin issued for WMO ESCAP Panel countries.

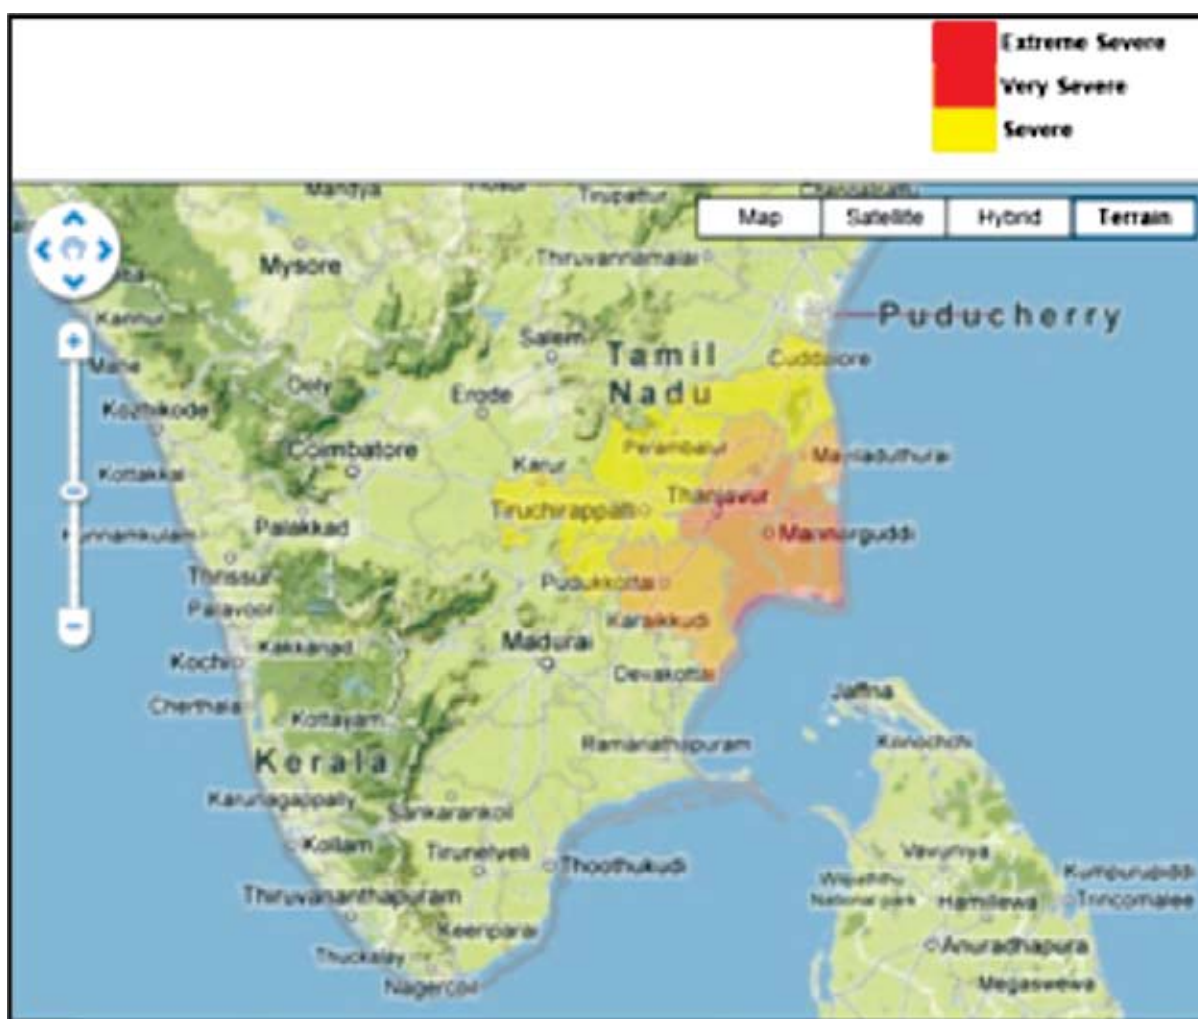

Fig. 6.8. A typical example of heavy rainfall warning graphics issued by IMD

6.6.9. Prognosis and Diagnosis

The prognostic and diagnostic features based on the prepared check list and decision making process is written at the end of the bulletin issued for WMO ESCAP Panel countries.

6.6.10. Significant Past Weather

Significant past weather is mentioned in the Bulletin for India coast. It is helpful for disaster management. It usually includes past 24 hr heavy rainfall recorded in different stations and also the gale wind observed in different places.

6.7. Damage Potential and Action Suggested in the Bulletin

The bulletin for India coast gives the expected damage and action suggested as given in Table 6.7.

6.8. Time of Issue of Bulletins

The time of issue of bulletin when the system is depression/cyclonic storm is given in Table 6.8 and 6.9.

In addition to the above mentioned table, the time of issue of Special Tropical Weather outlook may be issued at any time depending upon the formation/landfall of depression. For example, if the depression forms/crosses coast/dissipates over the sea at 0900 UTC, then the special tropical weather outlook can be issued based on 0900 UTC observation.

6.9. Numbering of Bulletins

The bulletins for India coast are numbered as follows. The first bulletin issued in connection with the second cyclonic disturbance over the Arabian Sea is given a number as ARB/2/1. The bulletin is further numbered from the issue of cyclone alert as cyclone alert No. 1, 2 etc., Cyclone warning No 1, 2, ... etc.

6.10. Reference Time

The reference time mentioned in the bulletin has the following meaning.

- Early Hours 0000 - 0400 Hrs. IST
- Morning 0400 - 0800 Hrs. IST
- Forenoon 0800 - 1200 Hrs. IST
- Afternoon 1200 - 1600 Hrs. IST
- Evening 1600 - 2000 Hrs. IST
- Night 2000 - 2400 Hrs. IST
- Early Morning 0400 - 0600 Hrs. IST
- Around Noon 1100 - 1300 Hrs. IST

6.11. Terminologies in the Bulletins

Some of the important terminology used in the bulletin pertain to description of sea condition, amount/ intensity of heavy rainfall, distribution of rainfall etc. These are presented in following Tables.

Table 6.7. Damage potential and action suggested in Bulletin for India coast

Intensity	Damage expected	Action Suggested
Deep Depression 50 – 61 kmph (28-33 knots)	Minor damage to loose and unsecured structures	Fishermen advised not to venture into the open seas.
Cyclonic Storm 62 – 87 kmph (34-47 knots)	Damage to thatched huts. Breaking of tree branches causing minor damage to power and communication lines	Total suspension of fishing operations
Severe Cyclonic Storm 88-117 kmph (48-63 knots)	Extensive damage to thatched roofs and huts. Minor damage to power and communication lines due to uprooting of large avenue trees. Flooding of escape routes.	Total suspension of fishing operations. Coastal hutment dwellers to be moved to safer places. People in affected areas to remain indoors.
Very Severe Cyclonic Storm 118-167 kmph (64-90 knots)	Extensive damage to kutchha houses. Partial disruption of power and communication line. Minor disruption of rail and road traffic. Potential threat from flying debris. Flooding of escape routes.	Total suspension of fishing operations. Mobilise evacuation from coastal areas. Judicious regulation of rail and road traffic. People in affected areas to remain indoors.
Very Severe Cyclonic Storm 168-221 kmph (91-119 knots)	Extensive damage to kutchha houses. Some damage to old buildings. Large-scale disruption of power and communication lines. Disruption of rail and road traffic due to extensive flooding. Potential threat from flying debris.	Total suspension of fishing operations. Extensive evacuation from coastal areas. Diversion or suspension of rail and road traffic. People in affected areas to remain indoors.
Super Cyclone 222 kmph and more (120 knots and more)	Extensive structural damage to residential and industrial buildings. Total disruption of communication and power supply. Extensive damage to bridges causing large-scale disruption of rail and road traffic. Large-scale flooding and inundation of sea water. Air full of flying debris.	Total suspension of fishing operations. Large-scale evacuation of coastal population. Total suspension of rail and road traffic in vulnerable areas. People in affected areas to remain indoors.

Table 6.8. Time of issue of bulletin when the system is depression/deep depression

Bulletin	Base Time	Issue Time	Base Time	Issue Time	Base Time	Issue Time	Base Time	Issue Time	Base Time	Issue Time	Base Time	Issue Time	Base Time	Issue Time	Base Time	Issue Time
Bulletin for Indian coast	0000	0300	0300	0600	0600	0900	0900	1200	1200	1500	1500	1800	1800	2100	2100	0000

***TC Vital	0000	0300			0600	0900			1200	1500			1800	2100		

* In addition to the above mentioned table, the time of issue of TCAC Bulletin may be issued at any time depending upon the formation of cyclonic storm/landfall of cyclone. For example if cyclonic storm forms/crosses the coast at 0900 UTC then the bulletin may be issued based on 0900 UTC observations.

** DGM bulletin may be issued at any time on the change of intensity/landfall of the system.

*** TC vital is issued from Deep Depression stage onwards.

Table 6.9. Time (UTC) of issue of bulletin when the system is cyclonic storm

CALM (RIPPLED)	0 - 0.1	1 - 3 (2 - 6)	1
SMOOTH (WAVELESS)	0.1 - 0.5	4 - 10 (7 - 19)	2 - 3
SLIGHT	0.5 - 1.25	11 - 16 (20 - 30)	4
MODERATE	1.25 - 2.5	17 - 21 (31 - 39)	5
ROUGH	2.5 - 4.0	22 - 27 (41 - 50)	6
VERY ROUGH	4.0 - 6.0	28 - 33 (52 - 61)	7
HIGH	6.0 - 9.0	34 - 40 (63 - 74)	8
VERY HIGH	9.0 - 14.0	41 - 63 (76 - 117)	9 - 11
PHENOMENAL	OVER 14	64 or above (119 or above)	12

Table 6.11. Distribution of Rainfall

Distribution	No. of Places	Description
Isolated	Isolated/One or two places	<25% of area gets rainfall
Scattered	A few places	(26 – 50)% of area gets rainfall
Fairly Widespread	Many places	(51 – 75)% of area gets rainfall
Widespread	Most places	(76 – 100)% of area gets rainfall

Table 6.12. Intensity of Rainfall

Descriptive term used	Rainfall amount in mm
No rain	0.0
Very light rain	0.1- 2.4
Light rain	2.5 – 7.5
Moderate rain	7.6 – 35.5
Rather heavy rain	35.6 – 64.4
Heavy rain	64.5 – 124.4
Very heavy rain	124.5 – 244.4
Extremely heavy rain	≥244.5
Exceptionally heavy rain	When the amount is a value near about highest recorded rainfall at or near the station for the month or season. However, this term will be used only when the actual rainfall amount exceeds 12 cm.

6.12. Check list for procedures

Due to the very heavy work load at the time of cyclone situations, utmost care should be taken not to miss any aspect of storm warning work. It is therefore essential

to have a check list so that warnings issued, etc., are systematically checked. Format given below is used as check list to ensure issue of appropriate warnings (Table 6.13).

Table 6.13(a). Check list of dissemination of bulletin by Cyclone Warning Division

Cyclone Warning Dissemination

7.1. Cyclone Warning Dissemination

Cyclone warnings are disseminated to various users through different means as mentioned below.

- ❖ Telephone
- ❖ Tele-fax
- ❖ VHF/HFRT
- ❖ Satellite based cyclone warning dissemination system (CWDS)
- ❖ Police Wireless
- ❖ AFTN (Aviation)
- ❖ Internet (e-mail)
- ❖ Websites
- ❖ Radio/TV network

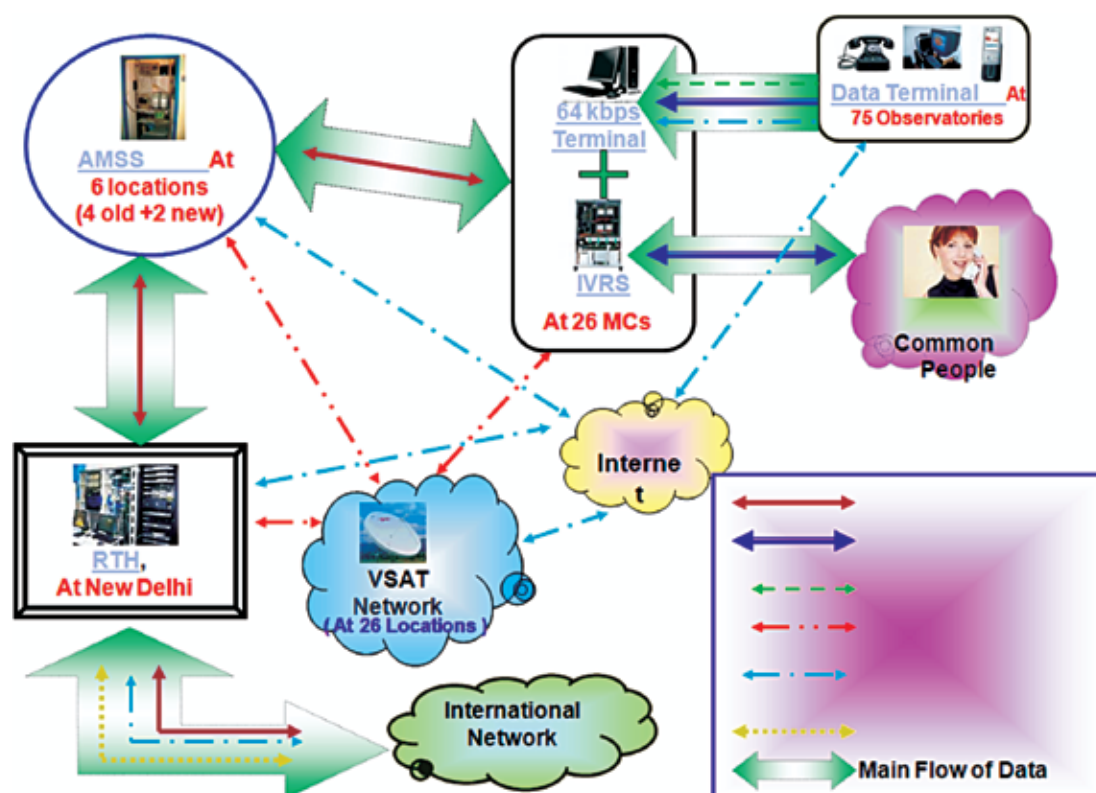

Fig. 7.1. Interactive Voice Response system

- ❖ Mobile Phones
- ❖ Interactive Voice Response System (IVRS)
- ❖ SMS

These warnings/advisories are put in the website, www.imd.gov.in of IMD. In IVRS (Fig.7.1), the requests for weather information and forecasts from general public are automatically answered. For this purpose, the person has to dial a toll free number “18001801717” from anywhere in the country. This system has been installed at 26 Meteorological Centres/ Regional Meteorological Centres. High Speed Data Terminals (HSDT) are installed at almost all MCs and RMCs. HSDTs are capable of sending short warning message as SMS and the whole warning message as email.

As telephonic communication often breaks down during cyclones, the warnings meant for the Chief Secretary and Collectors of coastal districts are passed on to these officials through police W/T channels, FAX or by telephone to ensure that the warnings reach these officials quickly to enable them to take precautionary measures promptly.

In addition, as a part of State Level Disaster Management Plan, VHF set is installed at ACWC, Mumbai and CWC, Bhubaneswar for quick communication to State Control Room. Police W/T personnel are made available with their equipments installed at ACWC Kolkata for transmission of warning messages to State Govt. authorities during cyclone and monsoon seasons every year.

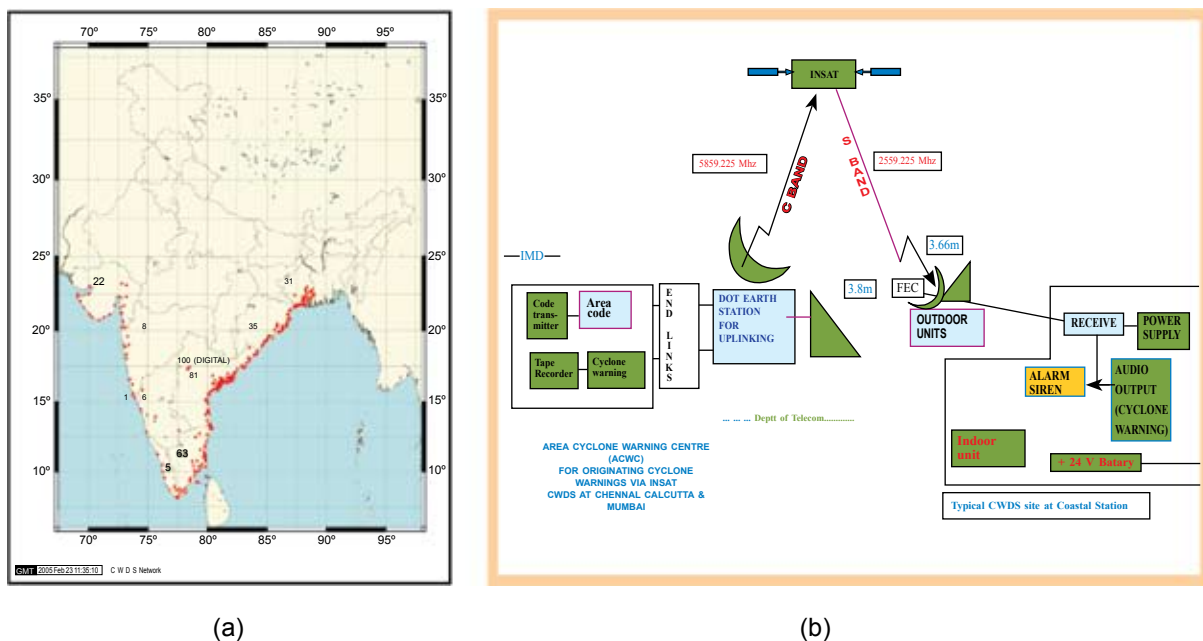

Fig. 7.2 (a). CWDS network and (b). block diagram of typical CWDS site at a coastal station

7.1.1. Cyclone Warning Dissemination System (CWDS)

In addition to the above network, for quick dissemination of warning against impending disaster from approaching cyclones, IMD has installed specially designed receivers within the vulnerable coastal areas for transmission of warnings to the concerned officials and people using broadcast capacity of INSAT satellite. This is a direct broadcast service of cyclone warning in the regional languages meant for the areas affected or likely to be affected by the cyclone. There are 352 Cyclone Warning Dissemination System (CWDS) stations along the Indian coast; out of these 101 digital CWDS are located along Andhra coast. The IMD's Area Cyclone Warning Centres (ACWCs) at Chennai, Mumbai & Kolkata and Cyclone Warning Centre (CWCs) at Bhubaneswar, Visakhapatnam & Ahmedabad are responsible for originating and disseminating the cyclone warnings through CWDS. The bulletins are generated and transmitted every hour. The cyclone warning bulletin is up-linked to the INSAT in C band (Fig.7.2).

For this service, the frequency of transmission from ground to satellite (uplink) is 5859.225 MHz and downlink is at 2559.225 MHz. The warning is selective and will be received only by the affected or likely to be affected stations. The service is

unique in the world and helps the public in general and the administration, in particular, during the cyclone season. Warning messages are received in local languages directly by CWDS receivers located in areas likely to be affected by the cyclone. It is a very useful system and has saved millions of lives and enormous amount of property from the fury of cyclones. The digital CWDS have shown good results and working satisfactorily.

7.1.2. Digital Meteorological Data Dissemination

IMD transmits processed imagery, meteorological and facsimile weather charts to field forecasting offices distributed over the country using the Digital Meteorological Data Dissemination (DMDD) facility, through INSAT in broadcast mode. The bulletins providing description of the cloud organization and coverage are also sent as advisory to forecasting offices every synoptic hour. When cyclones are detected in satellite imagery, these bulletins are sent every hour. Such advisories are also transmitted to the neighbouring countries.

Processed satellite imagery, analyzed weather charts and conventional synoptic data are up-linked to the satellite in C-band. Satellite broadcasts these data to DMDD receiving stations in S-band. DMDD receiving stations analyze weather

imagery and other data to generate required forecast. There are 37 no. of DMDD stations installed in India. Three DMDD receiving stations are also operating in neighbouring SAARC countries at Sri Lanka, Nepal and Maldives. These

stations are receiving direct broadcast of cloud imagery, weather facsimile charts and meteorological data on an operational basis. The frequency of transmission from ground to satellite (uplink) is 5886 MHz and that of downlink is 2586 MHz.

8

Pre-cyclone Exercise

The following are the instructions for action to be taken in the months preceding the pre and post -monsoon cyclone seasons (i.e. by about April and September) of each year.

8.1. Telecommunications

- (1) The Director in-charge at the ACWC/CWC will contact personally the General Manager-Telephones, General Manager-Maintenance and Senior officials in-charge of telefax/mobile/internet communication systems at their respective stations and ensure that :
 - a) the local communication links at the ACWC/CWC consisting of Telephone/Telefax/mobile/internet connections are maintained in good working condition, especially during the days of cyclonic storms.
 - b) the telecommunication circuits connecting the station to other Meteorological Offices are maintained at highest efficiency. They may also be requested to designate local officers to serve as liaison officers for this purpose so that they can be contacted at times of breakdown to ensure quick service.

- (2) Telefax machines at the stations should be maintained in good working condition. Essential spare parts should be requisitioned well in time and kept in store so that no breakdown occurs in the crucial time for want of these; maintenance staff also should be available on the spot during days of disturbed weather for immediate rectification of faults.
- (3) Police W/T: Any action required in connection with the issue of warnings through Police W/T should be completed. In particular, any shortcomings in this mode of communications noticed in the previous storm season should be discussed with the State Government authorities and remedial action should be taken.

8.2. Publicity and Broadcast of Warnings

Posters and Films

The ACWCs/CWCs should write to the State Government officials concerned for giving publicity to the people in the coastal districts about cyclones through cyclone posters and exhibition of the film on cyclones.

Radio and TV Talks

Talks on radio and television should be arranged by the ACWCs and CWCs on the hazards of cyclones and precautionary measures to be taken before, during and after the storms. The system of warnings should be explained.

All India Radio

The station Directors of All India Radio station in the concerned State(s) should be alerted about the broadcast of cyclone warnings through AIR and to ensure that the stations keep extended watch for broadcast of additional weather bulletins whenever required. They should be requested to include storm warning bulletins in their Vividh Bharati broadcasts and FM Channel also at frequent intervals as these have popular appeal.

Newspapers

Proper liaison should be established with local newspapers for prompt publication of latest warnings.

8.3. Observational Data and Organisation

Inspection of Coastal Observatories

All the coastal observatories and co-operative cyclone reporting network of stations (as well as Police W/T stations in Tamil Nadu) should be inspected once in a year during April or September to ensure

that the instruments at these stations are in good condition and the observers are familiar with correct recording and reporting of observations. If any persistent error is noticed in the recording or reporting, the observer should be immediately instructed. Similarly, where the observatory sends its observations to the MC/RMC through W/T, telephone/FAX/e-mail, the communication aspects should also be checked up.

Radar and DMDD

Any deficiency in the operation of the cyclone detection radars, RS/RW and DMDD stations in the region should be immediately brought to the notice of DDGM (UI)/ DDGM (Satellite Meteorology) by the MC/RC concerned for immediate rectification. Maintenance of SDUC equipment and satellite equipment should be done by DDGM (Sat. Met.) New Delhi.

8.4. Reference Publications and Forms

Relevant reference publications, such as, Code of storm warning signals for use at Indian maritime ports, Weather services to shipping, fishing vessels and maritime interests, the tide tables for the year, storm track atlas, code books, cyclone manual and required nomograms and T-classification tables for interpreting and assessing storm intensity from satellite pictures, etc., should be made readily available for storm warning work. Sufficient

stock of all special type of charts and forms required for cyclone work should be kept at the ACWCs/CWCs/CWD.

8.5. Cyclone Manual

As a part of the pre-storm season exercise, the officers and staff of ACWCs/CWCs/CWD engaged in storm warning work may go through the chapters of Cyclone Manual before each storm season and refresh themselves with the various procedures, so that procedural mistakes are totally avoided in operational work. A few informal classes should also be conducted for the benefit of persons newly posted to storm warning work. All the officers and members of staff should make themselves familiar with the list of various types of warnees to be warned and the formats in which these warnings are to be issued. The Action Books may be checked up to ensure that all the items listed there are updated. The formats of the various warnings should also be kept ready for reference.

8.6. Telephone Fax and E-mail Address

The telephone, V-Sat, Fax, E-mail, mobile nos., addresses etc. of different ACWCs/CWCs/ Radar stations and other concerned offices such as local Doordarshan, AIR, Chief Secretary, Revenue Secretary, SRC, State Disaster Mitigation Authority, Port offices, Fisheries officials should be readily available. In addition to above, the CWD should also maintain above updated

information in respect of national level disaster management agencies including NDM, NDMA etc.

8.7. Staff Matters

For relieving the heavy stress and strain on the forecasters in storm warning centres during storm period, CWD/ACWCs/CWCs should build up a reserve of personnel in the cadre of officers at these centres by training personnel working in the other units in storm warning work. For this purpose, all these persons may attend the forecasting work one day in a week by turn. Similar steps may be taken in CDRs to train reserve personnel wherever possible.

It is also essential that the staff posted at ACWCs/CWCs and coastal observatories are quite familiar with the various procedures connected with the cyclone warning work. The best available staff may be utilised in connection with storm warning work in view of its importance to the public. Sanctioning of leave to the staff engaged in operational forecasting work may be regulated to ensure availability of required number of trained and experienced persons for storm warning work.

8.8. Circular Letter to Warnees

Warnees to Listen to AIR

A circular letter is issued every year by about March or April and September by the ACWC/CWC informing the warnees

that whenever they receive the first warning for cyclone, they may commence listening to the regional All India Radio Stations for latest information about the storm and its further movement and intensification.

Action Taken by Warnees

The action taken by the warnees on receipt of our warning messages should also be obtained from them by asking them through a circular letter to send the monthly statements in the required proforma (OBS 213 forms). Such action as may be necessary on these statements has to be taken by the concerned ACWC/CWC. The warnees have to be supplied with the forms every year.

Circular Letter to Chief Secretaries

A circular letter may be sent to the Chief Secretaries of maritime states for designating officers of these states for liaison with the storm warning centres on behalf of the State Government during cyclone periods.

Circular Letter to the Port Officers

In the beginning of each cyclone season, the port officers are informed through a circular letter that they would be getting port warning messages from the ACWC/CWC whenever occasion demands. After the receipt of the first message at the port, the ports are expected to get at least one message in 24 hours in the case of

distant signals or more frequently whenever local signals are hoisted, till the advice for lowering the signals is received. In case, a port officer fails to receive such messages in time after the receipt of the first message, he has to take the initiative in contacting the ACWC/CWC to find out the actual position.

8.9. Ports

Visit to Ports

The ports are visited at least once in two years by officers who are well conversant with storm warning work. Usually, one of the officers of the ACWC/CWC proceeds on these tours as he will be in the best position to keep liaison with ports receiving storm warnings. He will also examine the arrangement for display of storm warning signals and also find out how effectively the storm warning system functioned particularly during periods of depressions or storms. The visiting officer will see that all the day and night signals are available and in proper condition, ready to be hoisted when warning telegrams to hoist them are received. After each visit, the officer submits a report about his visit incorporating his suggestions for the improvement of the warning system. The form of Hand-book of Ports is also filled up by the Officer and these reports are to be sent to the concerned ACWC for consolidation and submission to DDGM(WF) with suitable recommendations for further action.

Guidelines

The following guidelines in connection with the visits to ports may be followed:

- i) Every port exhibiting signals should normally be visited once in two years.
- ii) The visits to the ports without signals are to be undertaken primarily to ensure that (a) satisfactory arrangements exist at these ports for the reception of warnings and (b) their prompt communication to the people concerned. It may, therefore, be useful to visit these ports also, say at least once in four or five years.
- (iii) Ports affected by a storm may also be specially visited as and when considered necessary in order to ascertain how the warning system functioned during the storm.
- (v) The visits to ports are to be treated more or less on a par with the inspection of observatories and may therefore be arranged for by the DDGM at their discretion.
- (vi) The programme of visit to ports may be forwarded to CWD and DDGM (WF)'s office before the tours are actually undertaken.
- (vii) In case, DDGM (WF)'s office at any time considers that a particular port should be visited for a special reason, the R.M.C. concerned will be advised.

Early Action

Action as suggested by the visiting officers in their inspection reports should be examined for early implementation as may be found necessary.

8.10 Meeting with the Chief Secretaries of the Maritime States

Participation in the Annual Conference of Collectors

The Officer-in-charge of the ACWCs/ CWCs/MCs connected with storm warning work will meet the Chief Secretaries of the concerned States every year to apprise them of our storm warning service. The Chief Secretaries of the maritime States may also be requested to invite the DDGM (RMCs) of Mumbai, Kolkata and Chennai for participating in the Annual conference of Collectors so that they can explain to the Collectors the functioning of the storm warning organisation and other details regarding the issue of warnings, etc., There can also be discussions between the Storm Warning Officers on the one hand and the State Government officials on the other for a better understanding and improvement of the storm warning system particularly regarding the dissemination of storm warning messages.

Meeting Chief Secretary

The officers-in-charge of ACWCs/CWCs/MCs connected with storm warning work should also meet the Chief Secretary whenever a new incumbent takes office.

8.11. Visit to Coastal Radio Station

When an official proceeds on tour to observatories, they may visit the coastal radio stations (if it functions there) and impress on the staff, the need to receive as

many ship's observations as possible and to pass them promptly to the Meteorological offices.

8.12. User's Workshop

The ACWC's and CWC's should organize the User's Workshop, preferably once in two years to apprise the User's about the cyclone warning activity of IMD and collect their comments and feedback for further improvement of cyclone warning services in the country.

9

Post Cyclone Action

The present procedures and instructions on the various items of post-cyclone action are described in this chapter.

9.1. Preliminary and Final Reports

Immediately after a storm crosses coast and weakens into a depression, a preliminary report is prepared and put up in the website within a week by CWD, New Delhi. The final report which will be prepared within a month will be arranged under the following heading:

- (1) Brief history of the storm.
- (2) Weather and damage caused.
- (3) Warnings to State Government officials.
- (4) Broadcasts of warnings over AIR (and T.V.).
- (5) Port warnings.
- (6) Fisheries warnings.
- (7) Adequacy and timeliness of warnings.
- (8) Performance of NWP and statistical models.
- (9) Forecast and Warning verification results

The brief history will contain an account of the system from the depression stage onwards including its intensification into a storm/ severe storm, landfall and subsequent weakening. Crucial observations, if any, should be briefly referred to. A tentative track of the cyclone as well as the path as tracked by the Cyclone Detection Radar (if the cyclone was under radar surveillance) should also be included.

The important points under *Weather and damage caused* to be covered under this heading are:

- i) Areas affected by severe weather associated with the storm-tidal waves, gales, heavy rainfall including floods. Districts, taluks, towns or villages worst affected may be specifically mentioned.
- ii) Extent of damage caused to (a) agricultural and garden crops (b) buildings, (c) railway tracks and stations, (d)Telegraphic and electrical poles and installations (e) highways, avenue trees etc. (f) Dams and minor irrigation (g) estimated loss of life (human as well as cattle), loss of property and people rendered homeless. (h) Damage to ships at ports and port installations. This should be based on available reports in newspapers, from

Touring Officer's report as well as from Government sources. However, the preliminary report should not be unduly delayed awaiting the Touring Officers' return to Head Quarters. Under *Warning to State Government Officials*, four Stage Warnings including pre-cyclone watch and post land fall outlook to State Government officials such as Chief Secretary, Collectors of Coastal Districts etc., should be given in this para briefly.

Specific mention should be made as to:

- (i) When the information about the cyclonic storm (viz., Pre-cyclone watch and "Cyclone Alert") was first conveyed to the Chief Secretary (ies) of the concerned State Government(s) and the coastal District Collectors.
- (ii) When the first numbered warning under the Four Stage Warning System was sent to the above officials
- (iii) The elements for which the warnings were issued and the number of times warnings were sent to them during the storm period.

Under *Broadcasts of Warnings over A.I.R.*, the information given here should cover:

- i) Special AIR Bulletins under the Four Stage warning system and the times of issue of the first and subsequent crucial bulletins as well as the total number of bulletins issued.

- ii) The number of hourly bulletins issued after the storm came within the range of cyclone detection radar and tracked with a high degree of confidence
- iii) Whether the watch hours of the A.I.R. station were extended and if so the period of extension.
- iv) The time of issue of the first coastal weather bulletin for broadcast in AIR news cycle from New Delhi and total number of such bulletins issued.

Under *Port Warnings*, the progression of signals hoisted at the various ports may be given. The first hoisting and subsequent lowering of Great Danger / Danger Signals should be mentioned.

Report on Fisheries Warnings should contain

- i) Whether appropriate warnings commensurate with the intensity of the system were included in the four routine daily AIR bulletins for fishermen and in the warnings for fisheries officials in the designated / registered pages.
- ii) Whether advice to fishermen not to venture into the sea was conveyed sufficiently early.

Under *Adequacy and timeliness of warnings*, it should include the verification report of forecasts issued by IMD. How far the warnings were timely and adequate should be mentioned. The effectiveness of the storm warning system has to be assessed

from the user's point of view by having personal discussion with the recipients of the different warnings. For this purpose, the DDGM should meet the Chief Secretary of the concerned state. The DDGM can travel by air without making a reference to H.Q. to meet the Chief Secretary and the concerned port officials, fisheries officials, etc. immediately after a cyclonic storm has hit the coastal areas. The touring Officer's report if available by this time should also be utilised. Newspaper comments and/or extracts of appreciation expressed by public/officials who were recipients of the warnings should be included.

To facilitate the preparation of the preliminary report the particulars of all warnings issued are to be tabulated by the ACWC/CWC in the format given in Appendix A.

9.2. Press Bulletin

Immediately after the system has crossed the coast, a special press bulletin highlighting the timely warnings given by the Department should be issued. The press bulletin may be issued by the DDGM and a copy sent to DDGM(WF) and DDGM(S).

9.3. Final Report

The preliminary report will be followed by a detailed final report to be prepared by the ACWC and sent to DDGM(WF), Pune with a copy to DDGM(S), New Delhi. Whenever

necessary, the CWC will send the relevant material in the required format to the parent ACWC for preparing the report. The final report will have 9 statements with the following contents;

1. History of the storm, its track, crucial observations that helped in assessing the intensity of the storm and details of damage caused.
2. Port warnings
3. Cyclone bulletins to local AIR stations and AIR New Delhi for News cycle.
4. Four Stage Warnings including pre-cyclone watch and post landfall outlook to State Govt. officials and warnings to fishermen.
5. Statement of special observations called for
6. Statement of air field warnings.
7. List of FAX messages.
8. In addition, a statement giving copies of log book entries indicating the action taken by the Meteorologist for alerting high ranking State Government officials responsible for taking precautions may also be sent as Statement VIII. Verification of forecast of rainfall and landfall (May be sent alongwith the brief report with Appendix B in case of cyclonic storm which do not cause any damage/serious damage.

9.4. Scrutiny of Action Taken by ACWC/CWC

It is also desirable that DDGM scrutinise the action taken by the ACWCs/ CWCs and bring to the notice of the persons concerned any major omissions or discrepancies either in the text of the warnings issued or the procedure followed. Such instances should also be brought to the notice of DDGM (WF) by the DDGM RMC while forwarding the reports together with their assessment on the timeliness and adequacy of the warnings issued by the ACWCs/CWCs. The final scrutiny will be carried out by DDGM (WF) Pune and the remarks will be sent to the ACWCs with a copy to DDGM(S) New Delhi. ACWC will send the relevant portions of DDGM (WF)'s remarks to the CWC whenever necessary. DDGM will also arrange to check up whether all the Designated / Registered warnees concerned have been warned in connection with the storm and point out omission, if any, in this regard to ACWC/ CWC, as warnings issued to Designated / Registered warnees are not included in any of the statements in the final report sent to DDGM (WF).

9.5. Visit of Officer to Cyclone Affected Areas

9.5.1. Assessment of Damage

Whenever a cyclonic storm/severe cyclonic storm, on striking coast, causes

considerable damage to life and property, an officer from the concerned region should be sent on tour to visit the affected areas to assess the nature and extent of the damage caused, both from the economic and scientific points of view. DDGM (WF) Pune and DDGM (S) New Delhi should be informed by FAX about the tour. The touring officer should visit the crucial locations in the storm-affected area, contact various State and Central Government officers and interview people to examine how effectively the storm warning system worked. He will submit his report to the DDGM immediately after his return from tour.

9.5.2. Purpose of Survey

The main purpose of a survey of the damage caused by the cyclones is to assess in greater detail than is possible with the available synoptic observations and press reports, the track, intensity and other characteristics of the storm and to evaluate the effectiveness of the warnings issued. The touring officer's report should, therefore, include the following:

- (i) Track followed by the storm.
- (ii) The 'eye' or calm centre and its characteristics
- (iv) Duration of the lull period
- (v) Areas affected by gales and relative strength of winds in the different quadrants.

- (vi) Estimate of the maximum wind speed
- (vii) Recession of the sea
- (viii) Storm surges
- (ix) Rainfall associated with the storm
- (x) Comments from the recipients of the warnings about accuracy and timeliness of the warnings;
- (xi) Suggestions and recommendations for the improvement of the storm warning system/ observational network, etc.

Keeping the above in view, the touring officer should try to obtain and keep a record of such information which will enable him to estimate, as quantitatively and objectively as possible, the above features associated with the storm. In order to assist the Meteorological Officer who goes for such a survey, detailed guidelines are available in SOP for Post-event Survey (SOP No.1/2013). It is also advisable that the officers at CWC and ACWCs go through the reports of such past surveys made earlier, to familiarise themselves with the work. The offices should also keep these touring officer's reports bound as permanent records as they contain valuable scientific data on storms, collected with great effort, which may be required in the future.

9.5.3. Annual Cyclone Review Meeting

The primary aim of these meetings is to recommend steps for further improvements in the storm warning service on the basis of the actual working of the system during the storm season of the previous year. Towards this end, discussions should centre around the following points regarding the storms of the year under review:

- 1 Accuracy and timeliness of the warnings issued by the different ACWCs/ CWCs.
- 2 Notable successes and failures.
- 3 Comments on unsatisfactory warnings, if any, and where possible, the manner in which they could be improved.
- 4 Adequacy or otherwise of data in each case, including ships observations, radar and satellite observations and aircraft reports.
- 5 Adequacy or otherwise of telecommunication facilities, both for receipt of data and dissemination of warnings.
- 6 Deficiencies, if any, in any other aspects of the organisation which require improvement.
- 7 Major synoptic problems, from the standpoint of analysis and prognosis, experienced in the different cases.

These may include steering, intensification and weakening of the systems, estimation of wind speed, storm surges, heavy rainfall etc.

9.5.4 Back-plotting and Re-analysis

After the storm is over, all the working charts have to be completed by back plotting the late data, ships' log etc. and the charts re-analysed in all the Storm Warning Centres.

Based on the re-analysis after back-plotting of charts and utilising additional information

available through touring officers' reports, radar and satellite pictures etc., the centres will be refixed and the tracks of the storms finalised at DDGM(WF)'s office and be presented in ACR meeting. It will be reviewed by a track finalization committee. The finalized track will be considered for official purposes and future records. The final storm accounts will be prepared by DDGM(WF)'s office and sent by March/April for publication in the July issue of 'Mausam' and the same will be considered by CWRC, Chennai for modifying the e-Atlas.

APPENDIX: A (Preliminary Report)

Action taken by ACWC/ CWC _____ on the _____
cyclonic storm of _____ (date)

Date	Time of chart UTC.	System, its intensity location & expected movement	Port Warnings	Four stage warnings (including Pre-cyclone watch and post land fall outlook) to State Government officials	Serially numbered cyclone bulletins to local AIR stations and coastal weather bulletins for News Cycle	Warnings to fishermen.
1.	2	3	4	5	6	7
			This column will show the ports warned, the signals at these ports and the time of issue of the warnings.	This column will show the collectors and Chief Secretaries warned, the elements for which they are warned and the area covered by the warnings (in terms of districts.) Time of issue _____ IST to _____ IST	This column will show the local AIR stations to whom the cyclone bulletins were sent, their serial number, the elements and area covered (The elements and area need not be repeated in this column if they are the same as in column 5). (Time of issue _____ IST to _____ IST) Also indicate whether coastal weather bulletins sent to AIR New Delhi for News Cycle and the times of issue.	This column will show the coastal areas warned (in terms of districts), the elements, AIR stations to which sent (Time of issue _____ IST to _____ IST)

APPENDIX – B (FINAL REPORT)**STATEMENT – 1****A BRIEF ACCOUNT OF THE STORM WITH TRACK OF THE STORM****STATEMENT – II****STATEMENT OF PORT WARNING MESSAGES**

Date	Time of issue of telegram IST	Chart on which based UTC.	Ports to which sent	Text of messages

STATEMENT – III**SPECIAL BULLETINS (INCLUDING COASTAL WEATHER) TO A.I.R. STATIONS**

Date	Time of issue of telegram IST	Chart on which based UTC.	A.I.R. Station to which sent	Text of messages

STATEMENT – IV**FISHERIES AND FOUR STAGE WARNINGS**

Date	Time of issue (IST)	Chart on which based UTC	Text of warning	To whom sent

STATEMENT - V**SPECIAL OBSERVATIONS CALLED FOR**

Date and time of requisition IST	Station	Observations called for		Frequency of observations
		From	To	
Example:				
140640	Puri	150600Z	181500 Z	Hourly
160850	Cuddalore	171500Z	190000 Z	3 Hourly

STATEMENT – VI**AIR FIELD WARNINGS**

Date	Time of issue UTC/IST	Text	Issued by (Forecasting Office)

STATEMENT – VII**LIST OF FAX MESSAGES AND STD CALLS HIGHER THAN URGENT**

Date	To whom	Purpose	Remarks

STATEMENT – VIII**COPIES OF LOG BOOK ENTRIES FOR ALERTING HIGH RANKING STATE GOVERNMENT OFFICIALS**

Date	Time	Official contacted	Text of Message	Mode of contact (telephone etc.)	By whom

STATEMENT – IX**VERIFICATION OF FORECAST OF RAINFALL**

A				
Date/time	Name of District	Forecast of heavy / very heavy rainfall/ex-tremely heavy rainfall	Actual	Percentage of accuracy
				Total :

Note : For verification of rainfall forecast DRMS data may be utilised.

VERIFICATION OF FORECAST OF GALE WIND

B				
Date/time	Name of District	Forecast of gale wind (kts/kmph)	Actual wind (kts/kmph)	Error

VERIFICATION OF FORECAST OF STORM SURGE

C				
Date/time	Name of District	Forecast of Storm surge height(m)	Actual Storm surge height(m)	Error

10

Management of Cyclone and Common Man

Inundations caused by storm surge, uprooting of trees and damage caused by that, flooding of low lying areas due to heavy rain and damage to houses and communication due to very strong winds are the devastations due to cyclone, which can not be protected by a common man and has to be mentally prepared to accept the loss. However, a common man can take many important precautionary steps to save life and property. Some of these steps are mentioned below.

10.1. Steps to be Taken Before the Cyclone

- (i) Check houses, secure loose tiles by cementing wherever necessary, repair doors and windows.
- (ii) Check the area around the house -remove dead or dying trees, anchor removable objects like lumber piles, loose bricks, garbage cans, sign-boards, loose zinc sheets etc.
- (iii) Keep some wooden boards ready so that glass windows can be boarded.
- (iv) Keep a hurricane Lantern filled with kerosene, flash light and enough dry cells.
- (v) Promptly demolish condemned buildings.
- (vi) Those who have radio sets should ensure that the radio is fully serviceable. In the case of transistors an extra set of batteries should be kept handy.

10.2. Steps to be Taken During the Cyclone

- (i) Keep your radio on and listen to latest weather warnings and advisories from the nearest AIR station. Pass the information to others.
- (ii) Avoid being misled by rumours. Pass only the official information you have got from the radio to others.
- (iii) Get away from low lying beaches or other locations which may be swept by high tides or storm waves. Leave sufficiently early before your way to high ground gets flooded. Do not delay and run the risk of being marooned.
- (iv) If your house is out of danger from high tides and flooding from the river, and it is well built, it is then probably the best place. However, please act promptly if asked to evacuate.
- (v) Be alert for high water in areas where streams of rivers may flood due to heavy rains.

- (vi) Board up glass windows or put storm shutters in place. Use good wooden planks Securely fastened. Make-shift boarding may do more damage than none at all. Provide strong suitable support for outside doors.
- (vii) If you do not have wooden boards handy, paste paper strips on glasses to prevent splinters flying into the house.
- (viii) Get extra food, especially things which can be eaten without cooking or with very little preparation. Store extra drinking water in suitably covered vessel.
- (ix) If you are in one of the evacuation areas, move your valuable articles to upper floors to minimise flood damage.
- (x) Have cyclone lantern, flash lights and/ or other emergency light in working condition and keep them handy.
- (xi) Check on everything that might blow away or be torn loose. Kerosene tins, cans, agricultural implements, garden tools, road signs and other objects become weapon of destruction in strong winds. Remove them and store them in a covered room.
- (xii) Be sure that a window or door can be opened on the lee side of the house i.e. the side opposite the one facing the wind.
- (xiii) Make provisions for children and adults requiring special diets.
- (xiv) If the centre of 'eye' of the storm passes directly over your place, there will be a lull in the wind and rain, lasting for half an hour or more. During this period stay in safe place. Make emergency repairs during the lull period if necessary, but remember that strong wind will return suddenly from the opposite direction, frequently with even greater violence.
- (xv) Be calm. Your ability to meet emergency will inspire and help others.

10.3. Steps to be Taken After Cyclone

- (i) They should remain in shelters until informed by those in charge that they may return home.
- (ii) Any loose and dangling wire from the lamp post should be strictly avoided.
- (iii) People should keep away from disaster areas unless they are required to assist.
- (iv) Anti-social elements should be prevented from doing mischief and reported to the police.
- (v) Cars, buses lorries and carts should be driven carefully.
- (vi) The houses and dwellings should be cleared of debris.
- (vii) The losses should be reported to the appropriate authorities.

- (viii) Relatives should be promptly informed about the safety of persons in the disaster area.

10.4. Linkage of IMD with Cyclone Disaster Management

IMD has established linkages/institutional arrangements with disaster management agencies both at the centre and in the states. During normal weather conditions four bulletins are transmitted to Control Room of National Disaster Management Division (NDM). In a case of depression developing over north Indian Ocean which has the potential to affect Indian coast, special bulletins at-least five times a day. When the system intensifies into a cyclonic storm, the cyclone warning bulletins are issued every three hourly. At present 4 stage warning procedure as discussed earlier is followed for issuing bulletins to NDM Control Room. When the system weakens or not going to affect Indian coast, a dewarning message is also issued to NDM Control Room. The cyclone warning bulletins are also passed

on to State Government Authorities/ District Collectors who are in constant touch with Cyclone Warning Centres. The centres and local committees consisting of various departments dealing with disaster management issues meet at the time of crisis and take necessary follow up actions with the input on warning from IMD.

The linkage between IMD and disaster management agencies exists in all stages, viz.,

- (i) Pre-cyclone preparedness during season
- (ii) Dying occurrence of cyclone
- (iii) Post-cyclone action stage

Further linkage also exists in the following

- (i) Capacity building through research and development, training and infrastructure development including construction of cyclone shelter etc and preparation of guideline for management of cyclone
- (ii) Hazard, vulnerability and risk analysis for cyclone disaster mitigation

11

Conclusions and Future Scope

The design of a TC warning system in IMD takes into consideration of the prevailing state of the meteorological science, the available technological means of communication, the built-up environment such as dwellings, socio-economic conditions, appropriateness of protective actions as well as the expectations of the society. To maximise relevance and effectiveness of the TC warning, strategies are formulated in respect of the design of the forecast, triggering mechanisms, coordination with disaster management agencies, warning products generation, presentation & dissemination. Scientific and technological advances in TC forecasting are translated into

effectiveness of TC warning. The forecast and warning operations and decision-making process is made by blending scientifically based conceptual models, meteorological datasets, technology and expertise.

IMD continuously expands and strengthens its activities in relation to observing strategies, forecasting techniques, disseminating methods and research relating to different aspects of TC to ensure most critical meteorological support through observations, analysis, predictions and warnings to disaster managers and decision makers not only in the country but also to the NIO rim countries.
